## Coreless Transformer Isolated Digital Output 8 Channel 0.625 A High-Side Switch

## **Product Highlights**

- Coreless transformer isolated data interface
- Galvanic isolation
- 8 High-side output switches 1.2A
- µC compatible 8-bit serial peripheral

## Features

- Interface CMOS 3.3/5V operation compatible
- Serial Interface
- High common mode transient immunity
- Short circuit protection
- Maximum current internally limited
- Overload protection
- Overvoltage protection (including load dump)
- Undervoltage shutdown with autorestart and hysteresis
- Switching inductive loads
- Common output disable pin
- Thermal shutdown with restart
- Thermal independence of seperate channels
- · Common diagnostic output for overtemperature
- ESD protection
- Loss of GNDbb and loss of V<sub>bb</sub> protection
- · Very low standby current
- · Reverse battery protection
- · Isolated return path for DIAG signal
- RoHS compliant

## **Typical Application**

- Isolated switch for industrial applications (PLC)
- All types of resistive, inductive and capacitive loads
- µC compatible power switch for 24V DC applications
- · Driver for solenoid, relays and resistive loads

## Description

The ISO1H816G is a galvanically isolated 8 bit data interface in PG-DSO-36 package that provides 8 fully protected high-side power switches that are able to handle currents up to 1.2 A.

An serial  $\mu$ C compatible interface allows to connect the IC directly to a  $\mu$ C system. The input interface is designed to operate with 3.3/5V CMOS compatible levels.

The data transfer from input to output side is realized by the integrated Coreless Transformer Technology.

### Pin Configuration and Functionality

#### Pin Configuration and Functionality

## 1.2 Pin Functionality

#### VCC (Positive 3.3/5V logic supply)

The VCC supplies the input interface that is galvanically isolated from the output driver stage. The input interface can be supplied with 5V.

#### DIS (Output disable)

The high-side outputs OUT0...OUT7 can be immediately switched off by means of the low active pin DIS that is an asynchronous signal. The input registers are also reset by the DIS signal. The output remains switched off after low-high transient of DIS, till new data is written into the input interface. Current Sink to GNDCC

#### CS (Chip select)

The system microcontroller selects the ISO1H816G by means of the low active pin  $\overline{\text{CS}}$  to activate the interface. Current Source to VCC

#### SCLK (Serial shift clock)

SCLK (serial clock) is used to synchronize the data transfer between the master and the ISO1H816G. Data present at the SI pin are latched on the rising edge of the serial clock input, while data at the SO pin is updated after the falling edge of SCLK in serial mode. Current Source to VCC

#### SI (Serial data input)

This pin is used to transfer data into the device. Data is latched on the rising edge of the serial clock. Current Sink to GNDCC

#### SO (Serial data output)

This pin is used when the serial interface is activated. SO can be connected to a serial input of a further IC to built a daisy-chain configuration. It is only activated if  $\overline{CS}$  is in low state, otherwise this output is in high impedance state.

## DIAG (Common diagnostic output for overtemperature)

The low active DIAG signal contains the OR-wired information of the separated overtemperature detection units for each channel. The output pin DIAG provides an open drain functionality that. A current source is also connected to the pin DIAG. In normal operation the signal DIAG is high. When overtemperature or Vbb below ON-Limit is detected the signal DIAG changes to low.

#### **GNDCC (Ground for VCC domain)**

This pin acts as the ground reference for the input interface that is supplied by VCC.

#### GNDbb (Output driver ground domain)

This pin acts as the ground reference for the output driver that is supplied by Vbb.

#### OUT0 ... OUT7 (High side output channel 0 ... 7)

The output high side channels are internally connected to Vbb and controlled by the corresponding data input.

#### TAB (Vbb, Positive supply for output driver)

The heatslug is connected to the positive supply port of the output interface.

## 3 Functional Description

#### 3.1 Introduction

The ISOFACE ISO1H816G includes 8 high-side power switches that are controlled by means of the integrated uС compatible SPI interface. The outputs OUT0...OUT7 are controlled by the data of the serial input SI. The IC can replace 8 optocouplers and the 8 high-side switches in conventional I/O-Applications as a galvanic isolation is implemented by means of the integrated coreless transformer technology. The µC compatible interfaces allow a direct connection to the ports of a microcontroller without the need for other components. Each of the 8 high-side power switches is protected against short to Vbb. overload. overtemperature and against overvoltage by an active zener clamp.

The diagnostic logic on the power chip recognizes the overtemperature information of each power transistor The information is send via the internal coreless transformer to the pin DIAG at the input interface.

## 3.2 Power Supply

The IC contains 2 galvanic isolated voltage domains that are independent from each other. The input interface is supplied at VCC and the output stage is supplied at Vbb. The different voltage domains can be switched on at different time. The output stage is only enabled once the input stage enters a stable state.

## 3.3 Output Stage

Each channel contains a high-side vertical power FET that is protected by embedded protection functions.

The continuous current for each channel is 1.2A (all channels ON).

## 3.3.1 Output Stage Control

Each output is independently controlled by an output latch and a common reset line via the pin DIS that disables all eight outputs and reset the latches. Serial data input (SI) is read on the rising edge of the serial clock SCLK. A logic high input data bit turns the respective output channel ON, a logic low data bit turns it OFF. CS must be low whilst shifting all the serial data into the device. A low-to-high transition of CS transfers the serial data input bits to the output buffer.

### 3.3.2 Power Transistor Overvoltage Protection

Each of the eight output stages has its own zener clamp that causes a voltage limitation at the power transistor when solenoid loads are switched off.  $\rm V_{ON}$  is then clamped to 47V (min.).

Figure 3 Inductive and overvoltage output clamp (each channel)

Energy is stored in the load inductance during an inductive load switch-off.

 $E_L = 1/2 \times L \times {I_L}^2$ 

Figure 4 Inductive load switch-off energy dissipation (each channel)

While demagnetizing the load inductance, the energy dissipation in the DMOS is

$$E_{AS} = E_{bb} + E_L - E_R = V_{ON(CL)} \times i_L(t)dt$$

with an approximate solution for  $R_L > 0\Omega$ ::

$$E_{AS} = \frac{I_L \times L}{2 \times R_L} \times (V_{bb} + |V_{ON(CL)}|) \times \ln\left(1 + \frac{I_L \times R_L}{|V_{ON(CL)}|}\right)$$

## 3.3.3 Power Transistor Overcurrent Protection

The outputs are provided with a current limitation that enters a repetitive switched mode after an initial peak current has been exceeded. The initial peak short circuit current limit is set to  $I_{L(SCP)}$  at  $T_j = 125^{\circ}$ C. During the repetitive mode short circuit current limit is set to  $I_{L(SCr)}$ . If this operation leads to an overtemperature condition, a second protection level ( $T_j > 135^{\circ}$ C) will change the output into a low duty cycle PWM (selective thermal shutdown with restart) to prevent critical chip temperatures.

Figure 5 Overtemperature detection

The following figures show the timing for a turn on into short circuit and a short circuit in on-state. Heating up of the chip may require several milliseconds, depending on external conditions.

Figure 6 Turn on into short circuit, shut down by overtemperature, restart by cooling

igure 7 Short circuit in on-state, shut down down by overtemperature, restart by cooling

## 3.4 Common Diagnostic Output

The overtemperature detection information are ORwired in the common diagnostic output block. The information is send via the integrated coreless transformer to the input interface. The output stage at pin DIAG has an open drain functionality combined with a current source.

Figure 8 Common diagnostic output

### 3.5 Serial Interface

The ISO1H816G contains a serial interface that can be directly controlled by the microcontroller output ports.

## 3.5.1 SPI Signal Description

 $\overline{\text{CS}}$  - Chip select. The system microcontroller selects the ISO1H816G by means of the  $\overline{\text{CS}}$  pin. Whenever the pin is in a logic low state, data can be transferred from the  $\mu$ C.

#### CS High to low transition:

·Serial input data can be clocked in from then on

•SO changes from high impendance state to logic high or low state corresponding to the SO bit-state

#### **CS** Low to high transition:

•Transfer of SI bits from shift register into output buffers, if number of clock signals was an integer multiple of 8

•SO changes from the SO bit-state to high impendance state

To avoid any false clocking the serial input pin SCLK should be logic high state during high-to-low transition of  $\overline{CS}$ . When  $\overline{CS}$  is in a logic high state, any signals at the SCLK and SI pins are ignored and SO is forced into a high impedance state. The integrated modulo counter that counts the number of clocks avoids the take over of invalid commands caused by a spike on the clock line or wrong number of clock cycles. A command is only taken over if after the low-to-high transition of the  $\overline{CS}$  signal the number of clock cycles is an integer multiple of 8.

**SCLK** - Serial clock. The system clock pin clocks the internal shift register of the ISO1H816G. The serial input (SI) accepts data into the input shift register on the rising edge of SCLK while the serial output (SO) shifts the output information out of the shift register on the falling edge of the serial clock. It is essential that the <u>SCLK</u> pin is in a logic high state whenever chip select CS makes any transition. The number of clock pulses will be counted during a chip select cycle. The received data will only be accepted, if exactly an integer multiple of 8 clock pulses were counted during CS is active.

**SI** - Serial input. Serial data bits are shifted in at this pin, the most significant bit first. SI information is read in on the rising edge of the SCLK. Input data is latched in the shift register and then transferred to the control buffer of the output stages.

**SO** - Serial output. SO is in a high impedance state until the CS pin goes to a logic low state. The data of the internal shift register are shifted out serially at this pin. The most significant bit will appear at first. The further bits will appear following the falling edge of SCLK.

## 3.5.2 SPI Bus Concepts

## 3.5.2.1 Independent Individual Control

Each IC with a SPI is controlled individually and independently by an SPI master, as in a directional point-to-point communication. The port requirements for this topology are the greatest, because for each controlled IC an individual SPI at the  $\mu$ C is needed (SCLK, CS, SI). All ICs can be addressed simultaneously with the full SPI bandwidth.

#### Figure 9 Individual independent control of each IC with SPI

## 3.5.2.2 Daisy-chain Configuration

The connection of different ICs and a  $\mu$ C as shown in Fig. 11 is called a daisy-chain. For this type of bustopology only one SPI interface of the  $\mu$ C for two or

more ICs is needed. All ICs share the same clock and chip select port of the SPI master. That is all ICs are active and addressed simultaneously. The data out of the  $\mu$ C is connected to the SI of the first IC in the line. Each SO of an IC is connected to the SI of the next IC in the line.

wether the transmitted data is valid or not. If four times serial data coming from the internal registers is not accepted the output stages are switched off until the next valid data is received.

## Figure 10 SPI bus all ICs in a "daisy chain" configuration

The µC feeds to data bits into the SI of IC1 (first IC in the chain). The bits coming from the SO of IC1 are directly shifted into the SI of the next IC. As long as the chip select is inactive (logic high) all the IC SPIs ignore the clock (SCLK) and input signals (SI) and all outputs (SO) are in tristate. As long as the chip select is active the SPI register works as a simple shift register. With each clock signal one input is shifted into the SPI register (SI), each bit in the shift register moves one position further within the register, and the last bit in the SPI shift register is shifted out of SO. This continous as long as the chip select is active (logic low) and clock signals are applied. The data is then only taken over to the output buffers of each IC when the CS signal changes to high from low and recognized as valid data by the internal modulo counter.

## 3.6 Transmission Failure Detection

There is a failure detection unit integrated to ensure also a stable functionality during the integrated coreless transformer transmission. This unit decides

**Functional Description** 

## 3.7 Serial Interface Timing

Figure 11 Serial interface

Figure 12 Serial input timing diagram

Figure 13 Serial output timing diagram

## 4 Electrical Characteristics

Note: All voltages at pins 2to 14 are measured with respect to ground GNDCC (pin 15). All voltages at pin 20 to pin 36 and TAB are measured with respect to ground GNDbb (pin 19). The voltage levels are valid if other ratings are not violated. The two voltage domains V<sub>CC</sub>, GND<sub>CC</sub> and V<sub>bb</sub>, GND<sub>bb</sub> are internally galvanic isolated.

## 4.1 Absolute Maximum Ratings

Note: Absolute maximum ratings are defined as ratings, which when being exceeded may lead to destruction of the integrated circuit. For the same reason make sure, that any capacitor that will be connected to pin 2 (VCC) and TAB (Vbb) is discharged before assembling the application circuit. Supply voltages higher than V<sub>bb(AZ)</sub> require an external current limit for the GNDbb pin, e.g. with a 15Ω resistor in GNDbb connection. Operating at absolute maximum ratings can lead to a reduced lifetime.

Parameter	Symbol	Limit Values

Parameter <sup>1)</sup>	Symbol	Liı	mit Valu	es	Unit	<b>Test Condition</b>
at $T_j = -25 \dots 125^{\circ}$ C, $V_{bb}=15\dots 30$ V, $V_{CC}=3.0\dots 5.5$ V, unless otherwise specified		min.	typ.	max.	-	
Initial peak short circuit current limit, each channel $T_i = -25^{\circ}C$ , $V_{bb} = 30V$ , $t_m = 700 \mu s$	I <sub>L(SCp)</sub>			4.5	A	
$T_j = 25^{\circ}C$			3.0			
$T_j = 125^{\circ}C$		1.4				
two parallel channels: <sup>3)</sup> four parallel channels: <sup>3)</sup>			current of on ne current of			
Repetitive short circuit current limit <sup>3)</sup>	I <sub>L(SCr)</sub>					
T <sub>i</sub> = T <sub>it</sub> (see timing diagrams)						
each channel:			2.2			
two parallel channels: <sup>3)</sup>			2.2			
four parallel channels: <sup>3)</sup>			2.2			
Output clamp (inductive load switch off) at $V_{OUT} = V_{bb} - V_{ON(CL)}$	V <sub>ON(CL)</sub>	47	53	60	V	
Overvoltage protection	V <sub>bb(AZ)</sub>	47				
Thermal overload trip temperature <sup>2) 3)</sup>	T <sub>jt</sub>	135			°C	
Thermal hysteresis <sup>3)</sup>	$\Delta T_{jt}$		10		К	

 Integrated protection functions are designed to prevent IC destruction under fault conditions described in the data sheet. Fault conditions are considered as "outside" normal operating range. Protection functions are not designed for continuos repetitive operation.

2) Higher operating temperature at normal function for each channel available

3) not subject to production test, specified by design

## 4.6 Diagnostic Characteristics at pin DIAG

Parameter	Symbol Limit Values		Limit Values		Unit	<b>Test Condition</b>
at $T_j = -25 \dots 125^{\circ}$ C, $V_{bb}=15\dots 30$ V, $V_{CC}=3.0\dots 5.5$ V, unless otherwise specified		min.	typ.	max.		
Common diagnostic sink current (overtemperature of any channel) $T_j = 135^{\circ}C$	I <sub>diagsink</sub>			5	mA	V <sub>DIAGON</sub> < 0.25 x VCC
Common diagnostic source current	I <sub>diagsource</sub>		100		μA	

## 4.7 Input Interface

Parameter	Symbol	Lir	nit Valu	ies	Unit	Test Condition
at $T_j$ = -25 125°C, $V_{bb}$ =1530V, $V_{CC}$ = 3.05.5V, unless otherwise specified		min.	typ.	max.		
Input low state voltage (SI, DIS, CS, SCLK)	V <sub>IL</sub>	-0.3		0.3 x V <sub>CC</sub>	V	
Inpu <u>t high state</u> voltage (SI, DIS, CS, SCLK)	V <sub>IH</sub>	0.7 x V <sub>CC</sub>		V <sub>CC</sub> + 0.3		
Inpu <u>t voltag</u> e hysteresis (SI, DIS, CS, SCLK)	V <sub>IHys</sub>		100		mV	
Output low state voltage (SO)	V <sub>OL</sub>	-0.3		0.25 x V <sub>CC</sub>	V	C <sub>L</sub> < 50pF, R <sub>L</sub> > 10kΩ
Output high state voltage (SO)	V <sub>OH</sub>	0.75 x V <sub>CC</sub>		V <sub>CC</sub> + 0.3		
Input pull down current (SI , DIS)	l <sub>Idown</sub>		100		μA	
I <u>np</u> ut pull up current (CS, SCLK)	-I <sub>lup</sub>		100			
$\label{eq:output} \hline \hline Output disable time (transition \overline{\text{DIS}} to logic low)^{1)2)} \\ \hline Normal operation \\ \hline Turn-off time to 10% V_{OUT} \\ \hline R_L = 47\Omega \\ \hline \end{array}$	t <sub>DIS</sub>		85	170	μs	
Output disable time (transition $\overline{\text{DIS}}$ to logic low) <sup>1)2)3)</sup> Disturbed operation Turn-off time to 10% V <sub>OUT</sub> R <sub>L</sub> = 47 $\Omega$	t <sub>DIS</sub>			230		

1) The time includes the turn-on/off time of the high-side switch and the transmission time via the coreless transformer.

2) If Pin DIS is set to low the outputs are set to low; after DIS set to high a new write cycle is necessary to set the output again.

3) The parameter is not subject to production test - verified by design/characterization

## 4.8 SPI Timing

Parameter	Symbol	Li	mit Valu	ies	Unit	<b>Test Condition</b>
at T <sub>j</sub> = -25 125°C, V <sub>bb</sub> =1530V, V <sub>CC</sub> = 3.05.5V, unless otherwise specified		min.	typ.	max.		
Serial clock frequency	f <sub>SCLK</sub>	DC		20	MHz	
Serial clock period (1/fclk)	t <sub>p(SLCK)</sub>	50			ns	
$\overline{\text{CS}}$ Setup time (falling edge of $\overline{\text{CS}}$ to falling edge of SCLK)	t <sub>css</sub>	5				
$\overline{\text{CS}}$ Hold time (rising edge of SCLK to rising edge of $\overline{\text{CS}}$ )	t <sub>CSH</sub>	10				
Data setup time (required time SI to rising edge of SCLK)	t <sub>su</sub>	6				
Data hold time (falling edge of SCLK to SI)	t <sub>HD</sub>	6				
SO Output valid time CL = 50pF	t <sub>VALID</sub>			20		
$\overline{\text{CS}}$ Disable time ( $\overline{\text{CS}}$ high time between two accesses)	t <sub>CSD</sub>	20			μs	
SO Output disable time	t <sub>SODIS</sub>			20	ns	

## 4.9 Reverse Voltage

Parameter	Symbol	Limit Values			Unit	<b>Test Condition</b>
at $T_j$ = -25 125°C, $V_{bb}$ =1530V, $V_{CC}$ = 3.05.5V, unless otherwise specified		min.	typ.	max.		
Reverse voltage <sup>1)2)</sup>	-V <sub>bb</sub>				V	
$R_{GND} = 0 \Omega$				1		
$R_{GND} = 150 \Omega$				45		
Diode forward on voltage	-V <sub>ON</sub>				-	
IF = 1.25A, $V_{Dx}$ = low, each channel	0.1			1.2		

1) defined by P<sub>tot</sub>

2) not subject to production test, specified by design

## 4.10 Isolation and Safety-Related Specification

Parameter	Value	Unit	Conditions	
Rated dielectric isolation voltage V <sub>ISO</sub>	500	V <sub>AC</sub>	1 - minute duration <sup>1)</sup>	
Short term temporary overvoltage	1250	V	5s acc. DIN EN60664-1 1)	
Minimum external air gap (clearance)	2.6	mm	shortest distance through air.	
Minimum external tracking (creepage)	2.6	mm	shortest distance path along body	
Minimum Internal Gap	0.01	mm	Insulation distance through insulation	

1) not subject to production test, verified by characterization; Production Test with 1100V, 100ms duration

## 4.11 Reliability
