

L6494

High voltage high and low-side 2 A gate driver

Description

MOSFETs or IGBTs.

active-low shutdown pin.

MOSFETs\IGBTs.

conditions.

material.

or DSP.

Datasheet - production data

The L6494 is a high-voltage device manufactured with the BCD6 "offline" technology. It is a single chip half-bridge gate driver for N-channel power

The high-side (floating) section is designed to stand a DC voltage rail up to 500 V, with 600 V

transient withstand voltage. The logic inputs are CMOS/TTL compatible down to 3.3 V for easy

interfacing control units such as microcontrollers

The device is a single input gate driver with

A, making the L6494 particularly suited for

The independent UVLO protection circuits present on both the lower and upper driving

sections prevent the power switches from being

The integrated bootstrap diode as well as all of the integrated features of this driver make the

Features

- Transient withstand voltage 600 V
- dV/dt immunity ± 50 V/ns in full temperature range
- Driver current capability:
 - 2 A source typ. at 25 °C
 - 2.5 A sink typ. at 25 °C
- Short propagation delay: 85 ns
- Switching times 25 ns rise/fall with 1 nF load
- Integrated bootstrap diode
- Single input and shutdown pin •
- Adjustable deadtime
- 3.3 V, 5 V TTL/CMOS inputs with hysteresis •
- UVLO on both high-side and low-side sections
- Compact and simplified layout
- Bill of material reduction
- Flexible, easy and fast design

Applications

- Motor driver for home appliances, factory automation, industrial drives and fans
- HID ballasts
- Induction heating
- Welding
- Industrial inverters
- UPS
- Power supply units
- DC-DC converters

Table 1. Pin description						
Pin no.	Pin name	Туре	Function			
1	IN	I	Output drivers logic input (is in phase with HVG and in opposition of phase with LVG)			
2	SD	-	Shutdown logic input (active-low)			
4	DT	Ι	Deadtime setting			
6	LVG ⁽¹⁾	0	Low-side driver output			
7	VCC	Р	Low-side section supply voltage			
11	OUT	Р	High-side (floating) section common voltage			
12	HVG ⁽¹⁾	0	High-side driver output			
13	BOOT	Р	High-side (bootstrapped) section supply voltage			
3	SGND	Р	Signal ground			
5	PGND	Р	Power ground			
8, 9, 10, 14	NC	-	Not connected			

The circuit guarantees less than 1 V on the LVG and HVG pins (at I_{sink} = 10 mA), with V_{CC} > 3 V. This allows omitting the "bleeder" resistor connected between the gate and the source of the external MOSFET normally used to hold the pin low. 1.

7 Bootstrap driver

A bootstrap circuitry is needed to supply the high voltage section. This function is usually accomplished by a high voltage fast recovery diode (*Figure 8*). In the L6494 an integrated structure replaces the external diode.

C_{BOOT} selection and charging

To choose the proper C_{BOOT} value the external MOS can be seen as an equivalent capacitor. This capacitor C_{EXT} is related to the MOS total gate charge:

Equation 1

$$C_{EXT} = \frac{Q_{gate}}{V_{gate}}$$

The ratio between the capacitors C_{EXT} and C_{BOOT} is proportional to the cyclical voltage loss. It has to be:

Equation 2

if Q_{qate} is 30 nC and V_{qate} is 10 V, C_{EXT} is 3 nF. With C_{BOOT} = 100 nF the drop is 300 mV.

If HVG has to be supplied for a long time, the C_{BOOT} selection has also to take into account the leakage and quiescent losses.

HVG steady-state consumption is lower than 120 μ A, so if HVG T_{ON} is 5 ms, C_{BOOT} has to supply 0.6 μ C. This charge on a 1 μ F capacitor means a voltage drop of 0.6 V.

The internal bootstrap driver gives a great advantage: the external fast recovery diode can be avoided (it usually has great leakage current).

This structure can work only if V_{OUT} is close to SGND (or lower) and in the meanwhile the LVG is on. The charging time (T_{charge}) of the C_{BOOT} is the time in which both conditions are fulfilled and it has to be long enough to charge the capacitor.

The bootstrap driver introduces a voltage drop due to the DMOS $R_{DS(on)}$ (typical value: 175 Ω). At low frequency this drop can be neglected. Anyway, the rise of frequency has to take into account.

The following equation is useful to compute the drop on the bootstrap DMOS:

Equation 3

$$V_{drop} = I_{charge} R_{DS(on)} \rightarrow V_{drop} = \frac{Q_{gate}}{T_{charge}} R_{DS(on)}$$

where Q_{gate} is the gate charge of the external power MOS, $R_{DS(on)}$ is the on resistance of the bootstrap DMOS and T_{charge} is the charging time of the bootstrap capacitor.

For example: using a power MOS with a total gate charge of 30 nC the drop on the bootstrap DMOS is about 1 V, if the T_{charge} is 5 $\mu s.$ In fact:

Equation 4

$$V_{drop} = \frac{30nC}{5\mu s} \cdot 175\Omega \sim 1V$$

 V_{drop} has to be taken into account when the voltage drop on C_{BOOT} is calculated: if this drop is too high, or the circuit topology doesn't allow a sufficient charging time, an external diode can be used.

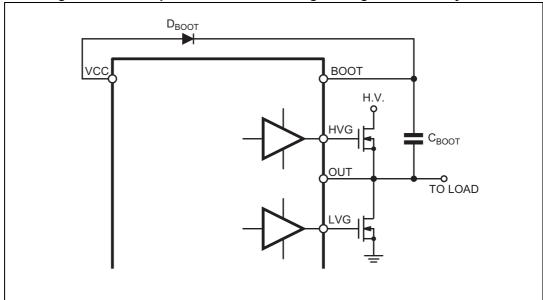

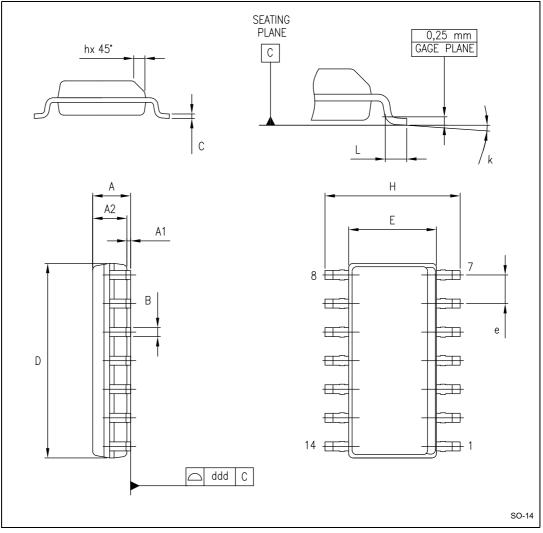

Figure 8. Bootstrap driver with external high voltage fast recovery diode

8 Package information

In order to meet environmental requirements, ST offers these devices in different grades of ECOPACK[®] packages, depending on their level of environmental compliance. ECOPACK[®] specifications, grade definitions and product status are available at: *www.st.com*. ECOPACK[®] is an ST trademark.
