

Ultra Series™ Crystal Oscillator (VCXO)

Si569 Data Sheet

Ultra Low Jitter I2C Programmable VCXO (100 fs), 0.2 to 3000 MHz

The Si569 Ultra Series™ voltage-controlled crystal oscillator utilizes Silicon Laboratories' advanced 4th generation DSPLL® technology to provide an ultra-low jitter, low phase noise clock at any output frequency. The device is user-programmed via simple I2C commands to provide any frequency from 0.2 to 3000 MHz with <1 ppb resolution and maintains exceptionally low jitter for both integer and fractional frequencies across its operating range. On-chip power supply filtering provides industry-leading power supply noise rejection, simplifying the task of generating low jitter clocks in noisy systems that use switched-mode power supplies. Unlike a traditional XO, where a different crystal is required for each output frequency, the Si569 uses one simple crystal and a DSPLL IC-based approach to provide the desired output frequency. The Si569 is factory-configurable for a wide variety of user specifications, including startup frequency, I2C address, output format, and OE pin location/polarity. Specific configurations are factory-programmed at time of shipment, eliminating long lead times associated with custom oscillators.

KEY FEATURES

- I2C programmable to any frequency from 0.2 to 3000 MHz with < 1 ppb resolution
- Ultra low jitter: 100 fs RMS Typ (12 kHz – 20 MHz)
- Configure up to 2 pin-selectable startup frequencies
- I2C interface supports 100 kbps, 400 kbps, and 1 Mbps (Fast Mode Plus)
- Excellent PSRR and supply noise immunity: –80 dBc Typ
- Programmable Kv (ppm/V) simplifies development
- 3.3 V, 2.5 V and 1.8 V V_{DD} supply operation from the same part number
- LVPECL, LVDS, CML, HCSSL, CMOS, and Dual CMOS output options
- 3.2x5, 5x7 mm package footprints
- Samples available with 1-2 week lead times

APPLICATIONS

- 100G/200G/400G OTN, coherent optics, PAM4
- 3G-SDI/12G-SDI/24G-SDI broadcast video
- Servers, switches, storage, search acceleration
- FPGA/ASIC clocking

Pin #	Descriptions
1	VC = Voltage Control Pin
2	Selectable via ordering option OE = Output enable; FS = Frequency Select
3	GND = Ground
4	CLK+ = Clock output
5	CLK- = Complementary clock output. Not used for CMOS.
6	VDD = Power supply
7	SDA = I2C Serial Data
8	SCL = I2C Serial Clock

1. Ordering Guide

The Si569 XO supports a variety of options including startup frequency, output format, and control voltage tuning slope, as shown in the chart below. Specific device configurations are programmed into the part at time of shipment, and samples are available in 1-2 weeks. Silicon Laboratories provides an online part number configuration utility to simplify this process. Refer to www.silabs.com/oscillators to access this tool and for further ordering instructions.

Notes:

- Contact Silicon Labs for non-standard configurations.
- Create custom part numbers at www.silabs.com/oscillators.
- Min Absolute Pull Range (APR) includes temp stability, initial accuracy, load pulling, VDD variation, and 20 year aging at 70 °C.
 - For best jitter and phase noise performance, always choose the smallest Kv that meets the application's minimum APR requirements. Unlike SAW-based solutions which require higher Kv values to account for their higher temperature dependence, the Si56x series provides lower Kv options to minimize noise coupling and jitter in real-world PLL designs.
 - Absolute Pull Range (APR) is the ability of a VCXO to track a signal over the product lifetime. A VCXO with an APR of ±20 ppm is able to lock to a clock with a ±20 ppm stability over 20 years over all operating conditions.
 - $APR (\pm) = (0.5 \times VDD \times \text{tuning slope}) - (\text{initial accuracy} + \text{temp stability} + \text{load pulling} + \text{VDD variation} + \text{aging})$.
 - Minimum APR values noted above include absolute worst case values for all parameters.
 - See application note, "AN266: VCXO Tuning Slope (Kv), Stability, and Absolute Pull Range (APR)" for more information.

		Swing (diff, F _{CLK} > 1.5 GHz) ⁶	0.3	0.55	0.9	V _{PP}
CMOS Output Option	V _{OH}	I _{OH} = 8/6/4 mA for 3.3/2.5/1.8V VDD	0.85 × V _{DD}	—	—	V
	V _{OL}	I _{OL} = 8/6/4 mA for 3.3/2.5/1.8V VDD	—	—	0.15 × V _{DD}	V

Notes:

1. Min APR includes ±20 ppm temperature stability, initial accuracy, load pulling, VDD variation, and aging for 20 yrs at 70 °C.
2. OE includes a 50 kΩ pull-up to VDD for OE active high, or includes a 50 kΩ pull-down to GND for OE active low. FS pin includes a 50 kΩ pull-up to VDD.
3. R_{term} = 50 Ω to V_{DD} – 2.0 V (see Figure 4.1).
4. R_{term} = 100 Ω (differential) (see Figure 4.2).
5. R_{term} = 50 Ω to GND (see Figure 4.2).
6. Refer to the figure below for Typical Clock Output Swing Amplitudes vs Frequency.
7. High drive LVDS swing is supported when following the method shown in section [5.8 Configuring High Drive LVDS Swing](#).

**Figure 2.1. Typical Clock Output Swing Amplitudes vs. Frequency**

Table 2.2. I2C Characteristics $V_{DD} = 1.8, 2.5, \text{ or } 3.3 \text{ V} \pm 5\%$, $T_A = -40 \text{ to } 85 \text{ }^\circ\text{C}$

Table 2.8. Absolute Maximum Ratings¹

Parameter	Symbol	Rating	Unit
Maximum Operating Temp.	T_{AMAX}	95	°C
Storage Temperature	T_S	–55 to 125	°C
Supply Voltage	V_{DD}	–0.5 to 3.8	°C
Input Voltage	V_{IN}	–0.5 to $V_{DD} + 0.3$	V
ESD HBM (JESD22-A114)	HBM	2.0	kV
Solder Temperature ²	T_{PEAK}	260	°C
Solder Time at T_{PEAK} ²	T_P	20–40	sec

Notes:

1. Stresses beyond those listed in this table may cause permanent damage to the device. Functional operation specification compliance is not implied at these conditions. Exposure to maximum rating conditions for extended periods may affect device reliability.
2. The device is compliant with JEDEC J-STD-020.

3. Dual CMOS Buffer

Dual CMOS output format ordering options support either complementary or in-phase signals for two identical frequency outputs. This feature enables replacement of multiple VCXOs with a single Si569 device.

Figure 3.1. Integrated 1:2 CMOS Buffer Supports Complementary or In-Phase Outputs

4. Recommended Output Terminations

The output drivers support both AC-coupled and DC-coupled terminations as shown in figures below.

Figure 4.1. LVPECL Output Terminations

AC-Coupled LVPECL Termination Resistor Values				DC-Coupled LVPECL Termination Resistor Values		
VDD	R1	R2	Rp	VDD	R1	R2
3.3 V	127 Ω	82.5 Ω	130 Ω	3.3 V	127 Ω	82.5 Ω
2.5 V	250 Ω	62.5 Ω	90 Ω	2.5 V	250 Ω	62.5 Ω

Figure 4.2. LVDS and HCSL Output Terminations

Figure 4.3. CML and CMOS Output Terminations

5. Configuring Si569 via I2C

The Si569 VCXO device contains a fixed frequency crystal and frequency synthesis IC using Silicon Labs patented DSPLL™ technology, all enclosed in a standard hermetically sealed voltage controlled crystal oscillator (VCXO) package. The internal crystal provides the reference frequency used by the DSPLL frequency synthesis IC. The center output frequency of the Si569 voltage controlled oscillator is set via I2C register settings in the DSPLL frequency synthesis IC. The output frequency is then pulled higher or lower by applying a voltage above or below $VDD/2$ to the VC pin. The amount of output frequency change per volt is based on a programmed ppm/V (Kv) register setting. DSPLL technology provides unmatched frequency flexibility with superior output jitter/phase noise performance and part per trillion frequency accuracy. This section describes how to calculate the required Si569 register values used to set device output frequency and Kv gain, and how to load these values into the Si569 device.

Figure 5.1. Si569 Block Diagram

The figure above is a simplified high-level block diagram of the Si569 VCXO device. The output frequency is set by a combination of three divider blocks highlighted in the above block diagram.

1. FBDIV - DSPLL™ Feedback Divider used to set Digital VCO frequency
2. HSDIV - High-Speed Output Divider
3. LSDIV - Low-Speed Output Divider

The final device output frequency (F_{out}) is based on the digital VCO frequency (F_{vco}) divided by the product of the HSDIV and LSDIV divider values. The digital VCO frequency is based on the crystal reference frequency (OSC) multiplied by the feedback divider setting (FBDIV). The FBDIV value is set via I2C registers and is modulated depending on the voltage on the Vc pin. The amount of digital VCO frequency variation for a given Vc voltage in ppm/V depends on the Kv register setting. The limits of each of these internal blocks (digital VCO and dividers) determines the valid operating frequency range of the device.

The FBDIV divider is a fractional fixed-point divider with a total length of 43 bits consisting of an 11-bit integer field (FBINT) and a 32 bit fractional field (FBFRAC) where total $FBDIV = [FBINT].[FBFRAC]$ with an implied decimal point as shown. This bit format is known as an 11.32 fixed point format where the integer portion is 11 bits and fractional portion is 32 bits, for a total of 43 bits.

The HSDIV divider is an integer divider, 11 bits in length, containing a binary divider value. One noteworthy feature of the HSDIV divider is a special duty cycle correction circuit that allows **odd** divide ratios of lower divider values (4-33 only) with 50% duty cycle output. This feature is useful when LSDIV divide ratio is set to 1.

The LSDIV divider performs power-of-2 divides ranging from divide by 1 (2^0) to divide by 32 (2^5). The register controlling the LSDIV divider is 3 bits in length, holding the power-of-2 divide ratio (divider exponent). For example, if the LSDIV register = 3 the LSDIV divide ratio is $2^3 = 8$. Note that LSDIV has a maximum value of 32 and therefore LSDIV register settings of 5, 6 or 7 will all result in the maximum divide-by-32 LSDIV operation.

The tables below summarize the divider limits for LSDIV, HSDIV, FBDIV. These limits and restrictions **must** be observed when deriving divider register values as will be explained in later sections.

Table 5.1. Si569 Divider Range Limits

Divider	Upper Limit	Lower Limit
HSDIV[10:0] (unsigned)	2046	4
LSDIV[2:0] ¹ (unsigned)	32 (2 ⁵)	1 (2 ⁰)
FBDIV[42:0] hex (unsigned)	7FDFFFFFFF	03C0000000
FBDIV[42:0] int.frac (unsigned)	2045.99999999976	60.0

Note:

1. LSDIV is power of 2 divider. See LSDIV table below for actual divide ratio based on LSDIV register value.

Table 5.2. Additional LSDIV and HSDIV Divider Restrictions

LSDIV Register Value	Divide Ratio	HSDIV Value Restrictions
0	1	4-33 even or odd values ¹ , 34-2046 even values only
1	2	4-2046 even or odd values
2	4	4-2046 even or odd values
3	8	4-2046 even or odd values
4	16	4-2046 even or odd values
5	32	4-2046 even or odd values
6	32	4-2046 even or odd values
7	32	4-2046 even or odd values

Note:

1. HSDIV can implement low value (4-33) **odd** divide ratios while providing a 50% duty cycle output due to special duty cycle correction circuit.

Note that all divider values (FBDIV, HSDIV, LSDIV) are **unsigned** and contain only positive values.

The Si569 high-performance VCXO family has four different speed grade offerings, each covering a specific frequency range. The table below outlines the output frequency range coverage by each speed grade, the corresponding min and max VCO frequency for that speed grade, and the nominal crystal frequency. The information in the table below is needed when calculating divider settings for a given device, speed grade, and output frequency.

Table 5.3. Si569 Speed Grades, Crystal Frequency, and VCO Range Limits

Device	Speed Grade	Xtal freq (MHz)	Min Output Freq (MHz)	Max Output Freq (MHz)	Min Fvco (GHz)	Max Fvco (GHz)
Si569	A	152.6	0.2	3000	10.8	13.122222022
	B	152.6	0.2	1500	10.8	12.511886114
	C	152.6	0.2	800	10.8	12.206718160
	D	152.6	0.2	325	10.8	12.206718160

5.1 Output Frequency and Kv Gain Calibration Equations

The basic equations used to derive the output frequency are given below and can be inferred from the device block diagram in [Figure 5.2 Si569 Frequency Definition Block Diagram on page 14](#). Equation 1 is the relationship between the output frequency (F_{out}), and the VCO frequency (F_{vco}) and total output divider ratio ($HSDIV \times LSDIV$). Equation 2 is the relationship between the VCO frequency (F_{vco}), the fixed crystal oscillator frequency (F_{osc}), and the feedback divider ($FBDIV$). Equation 2 also includes frequency adjustment (Δf) using the input control voltage (V_c) and the ppm/V control voltage gain (K_v).

$$F_{out} = F_{vco} / (HSDIV \times LSDIV)$$

Equation 1

$$F_{vco} = (F_{osc} \times FBDIV) \times (1 + \Delta f) \text{ (offset freq in ppm)}$$

Equation 2a

$$F_{vco} = (F_{osc} \times FBDIV) \times (1 + [(V_c - VDD/2) \times K_v])$$

Equation 2b

Figure 5.2. Si569 Frequency Definition Block Diagram

Equation 3a is a rearranged Equation 1 to solve for the total output divider ($HSDIV \times LSDIV$) given F_{out} and F_{vco} . Equation 3b is rearranged again solving for F_{vco} given F_{out} and ($HSDIV \times LSDIV$).

$$(HSDIV \times LSDIV) = F_{vco} / F_{out}$$

Equation 3a

$$F_{vco} = F_{out} \times (HSDIV \times LSDIV)$$

Equation 3b

Equation 4a is a rearranged Equation 2b to now solve for $FBDIV$ given F_{vco} , V_c , VDD , K_v , and F_{osc} . Equation 4b simplifies Equation 4a to determine the $FBDIV$ value for the center output frequency when $V_c = VDD/2$.

$$FBDIV = (F_{vco} / F_{osc}) / [1 + (V_c - VDD/2) \times K_v]$$

Equation 4a

$$FBDIV = F_{vco} / F_{osc} \text{ for } V_c = VDD/2 \text{ (center frequency)}$$

Equation 4b

Equations 3a, 3b, 4a, and 4b will be used in the process of deriving the required divider values to provide a desired center output frequency (F_{out}). The basic process is outlined in the next section.

Whenever the F_{vco} frequency is modified from the factory default, it is necessary to re-calibrate K_v gain. This is because the V_c ADC input sampling rate is tied to F_{vco} and is factory calibrated to 80 MHz based on the factory F_{vco} setting. Whenever F_{vco} is modified to change the output center frequency, the V_c ADC sampling rate is also changed so the full-scale K_v gain must be re-calculated.

$$\text{CADC_FSGAIN} = \text{round} (128 * \text{nominal Vc ADC sampling rate} / \text{new Vc ADC sampling rate})$$

Equation 5a

$$\text{CADC_FSGAIN} = \text{round} (128 * 80\text{e}6 / (\text{Fvco} / \text{NFXDIV} / 8))$$

Equation 5b

Equations 5a and 5b are used along with the table below to re-calculate the Kv full scale gain. This process is also outlined in the next section.

Table 5.4. Si569 NFXDIV Values for Different FBDIV Integer Values

FBDIV Min	FBDIV Max	NFXDIV Value
—	71.999999...	16
72.000000...	78.999999...	18
79.000000...	85.999999...	20
86.000000...	—	22

5.2 General Process Steps for Divider Calculations and Kv Gain Calibration

1. Estimate a theoretical total output divider value (HSDIV * LSDIV) based on desired Fout while targeting the minimum valid Fvco frequency using Equation 3a and [Table 5.3 Si569 Speed Grades, Crystal Frequency, and VCO Range Limits on page 13](#). Use floating point calculations for this step.
 - Result: Floating point value of total output divider (HSDIV * LSDIV) for Fvco minimum.
2. Derive a valid LSDIV divider value based on LSDIV and HSDIV divider limitations. Use the lowest possible integer value for LSDIV. For example, if the floating point output divider (HSDIV * LSDIV) for Fvco minimum = 8.22, use LSDIV = 1 and HSDIV = 8.22 versus LSDIV = 2 and HSDIV = 4.11.
 - Result: Valid integer LSDIV value.
3. Using the LSDIV value from #2 above, find the nearest valid **integer** HSDIV divider value resulting in Fvco being **equal to or greater than Fvco min**, observing all HSDIV limitations. Use Equations 3a/3b as necessary.
 - Result: Valid integer HSDIV value.
4. With valid integer HSDIV and LSDIV values, calculate the target Fvco center frequency with Equation. 3b. (Fvco must remain in the valid range per [Table 5.3 Si569 Speed Grades, Crystal Frequency, and VCO Range Limits on page 13](#).)
 - Result: Valid Fvco frequency.
5. With the derived valid Fvco frequency, use Equation 4b to calculate the required FBDIV based on the device specific Fosc frequency from [Table 5.3 Si569 Speed Grades, Crystal Frequency, and VCO Range Limits on page 13](#). Assume Vc = VDD/2 to calculate an FBDIV value for the center Fout frequency.
 - Result: Valid fractional FBDIV value
6. At this point all FBDIV, HSDIV and LSDIV values required to generate the desired center output frequency have been calculated. These three divider values must be now be appropriately formatted to fit the register format expected by the device. This is described in a later section.
 - Result: Valid register values for FBDIV, HSDIV, LSDIV
7. To re-calibrate Kv gain, first determine the integer portion of the new FBDIV value in step #5 above using truncation (not rounding) and then use that value to select the correct NFXDIV value using [Table 5.4 Si569 NFXDIV Values for Different FBDIV Integer Values on page 15](#).
 - Result: Valid NFXDIV value
8. To complete Kv gain calibration, calculate the new Kv gain calibration value (CADC_FSGAIN) using Equation 5b. This Kv gain calibration value must be appropriately formatted to fit the register format expected by the device. This is described in a later section.
 - Result: Valid CADC_FSGAIN value

5.3 Example: Deriving Si569 Divider Settings for 156.75 MHz Output

The general process of deriving divider values for a specific output frequency is outlined in the previous section and now will be used in this example. To reiterate, all calculations must be done while observing divider limits and valid VCO frequency range limits for your device. In this example, the device is Si569 and with a desired output frequency of 156.75 MHz, the speed grade required will be "D" or better. (One important note: All divider and register settings derived for any speed grade will work without modification for all **faster** speed grades on the same base part number device.)

Example VB code that implements the following divider calculation process is given in [5.10 Si569 Frequency Planner VB Code](#) and can be used for implementing any supported output frequency.

Step 1: Find the valid theoretical lower limit of the total output divider (HSDIV*LSDIV) based on the desired output frequency and lowest valid VCO frequency. This will bias the divider solution to the lowest possible VCO frequency since this will provide the best performance solution.

Given the valid Si569 VCO range is 10.8000 GHz to 12.206718160 GHz, the minimum theoretical values for (HSDIV * LSDIV) for the example 156.75 MHz output frequency are given in Equation 3:

$$\text{Minimum (HSDIV*LSDIV)} = (10.8000 \text{ GHz} / 156.75 \text{ MHz}) = \underline{\underline{68.89952\dots}}$$

Step 2: Find valid LSDIV divisor value given minimum (HSDIV*LSDIV) from step 1. For best performance, preference should be given to implementation of the total output divider (HSDIV*LSDIV) using HSDIV with LSDIV divide ratio = 1, if possible. Use LSDIV divide ratios > 1 only if HSDIV alone cannot implement the required output divider. Since the total (HSDIV*LSDIV) value of 68.8995... is less than the HSDIV maximum divider value of 2046, the LSDIV divide **ratio** value will be 1, which corresponds to a LSDIV register setting of 0, since the LSDIV divider can only be a power of 2 value (see [Table 5.2 Additional LSDIV and HSDIV Divider Restrictions on page 13](#) for valid LSDIV settings).

$$\text{LSDIV divide ratio} = \underline{1}, \text{ therefore } \text{LSDIV register value} = \underline{0}$$

Step 3: Find HSDIV divisor value. Given LSDIV = 1, HSDIV must implement 68.8995... or greater. Since HSDIV is an integer divider, the next greatest integer is 69. But, checking valid HSDIV values when LSDIV divide ratio = 1, we see 69 is NOT valid since it is greater than 33 and an odd value. This means the next greater integer value must be used, which is 70 (now even value). Note that 68 would **not** be valid since 68 is less than 68.8995... and would result in a VCO frequency below the lower VCO frequency limit.

$$\text{HSDIV divide ratio} = \underline{70}, \text{ which gives } \text{HSDIV register value} = \underline{70} \text{ decimal (or hex value} = \underline{0x46})$$

Step 4: Calculate a valid VCO frequency and corresponding floating point FBDIV value. Given the calculated output divider value (HSDIV*LSDIV) = 70, the VCO frequency must be set to (156.75 MHz * 70) = **10.9725 GHz**. Note that 10.9725 GHz is indeed within the valid VCO frequency range per [Table 5.3 Si569 Speed Grades, Crystal Frequency, and VCO Range Limits on page 13](#).

$$\text{Fvco} = \underline{\underline{10.9725 \text{ GHz}}}$$

Step 5: Calculate the FBDIV value necessary to provide a 10.9725 GHz Fvco using a 152.6 MHz crystal as reference (Si569 device). The floating point FBDIV value required to attain 10.9725 GHz with a 152.6 MHz crystal reference can be calculated as follows:

$$\text{FBDIV (float)} = 10.9725 \text{ GHz} / 152.6 \text{ MHz} = \underline{\underline{71.9036697247707}}$$

Step 6: Format each divider value into the required register format. LSDIV and HSDIV are simply binary values and can be directly used. FBDIV must first be put into 11.32 fixed point format. Converting the floating point FBDIV value into the 11.32 fixed point hex value required by the Si569 is done as follows:

Integer value = **71** decimal. Convert **71** to 11 bit hex = **0x047**. This is FBINT.

Fractional value = **0.9036697247707**. Multiply fractional value by $2^{32} = 3881231914.2752$. Now extract only the **integer** part of the result which is 3881231914. Convert 3881231914 to 32 bit hex = **0xE756E62A**. This is FBFRAC.

The resulting 11.32 fixed point hex number is therefore:

$$\text{FBDIV} = \text{FBINT.FBFRAC} = \underline{\underline{0x047E756E62A}}$$

At this point we have calculated all the required divider values. The table below summarizes the resulting divider values for implementing a 156.75 MHz output clock on the Si569.

Table 5.5. Divider Register Values for Si569 Configured for 156.75 MHz Output Clock

Divider Register	Decimal Value	Hex Value	Reg Length (bits)
LSDIV	0	0x0	3
HSDIV	70	0x046	11
FBDIV	71.9036697247707	0x047E756E62A	43 (11+32)

5.4 Example: Deriving Si569 Kv Gain Settings for 156.75 MHz Output

Whenever the Fvco frequency is modified from the factory default it is necessary to re-calibrate Kv gain.

Step 1: Find the Fvco and FBDIV values from the new configuration to be used for Equation 5b.

$$F_{vco} = \underline{10.9725 \text{ GHz}}$$

$$FBDIV (\text{float}) = 10.9725 \text{ GHz} / 152.6 \text{ MHz} = \underline{71.9036697247707}$$

Step 2: Use the integer portion of FBDIV to find the correct value for NFXDIV using [Table 5.4 Si569 NFXDIV Values for Different FBDIV Integer Values on page 15](#). Do not round up the integer portion of FBDIV, instead truncate FBDIV down via the floor function.

$$FBDIV (\text{int}) = \text{floor} (10.9725 \text{ GHz} / 152.6 \text{ MHz}) = \text{floor} (71.9036697247707) = \underline{71}$$

Excerpt from [Table 5.4 Si569 NFXDIV Values for Different FBDIV Integer Values on page 15](#):

FBDIV Min	FBDIV Max	NFXDIV Value
—	71.999999...	16
72.000000...	78.999999...	18

Step 3: Calculate the new CADC_FSGAIN calibration value using Fvco, FBDIV (int) and NFXDIV.

$$CADC_FSGAIN = \text{round} (128 * 80e6 / (F_{vco} / NFXDIV / 8))$$

$$CADC_FSGAIN = \text{round} (128 * 80e6 / (10.9725e9 / 16 / 8))$$

$$CADC_FSGAIN = \text{round} (119.455) = \underline{119} = \underline{0x77}$$

5.5 Mapping Divider Settings into Register Values

For the previous 156.75 MHz example, the divider value to register mapping is shown in the table below. Note that Register 24 is a packed register and contains bits from both LSDIV and HSDIV registers as follows: LSDIV[2:0] maps into Reg24[6:4] and HSDIV[10:8] maps into Reg24[2:0]. Note that bits Reg24[7] and Reg24[3] are not used and indicated with 'x' in the RegName field below. See also the Register Map Reference section for specific bit positioning within registers.

Table 5.6. Si569 Divider Register Values for 156.75 MHz Output Clock Configuration

Register (Decimal)	Hex Value	Reg Name
23	46	HSDIV[7:0]
24	00	x:LSDIV[2:0]:x:HSDIV[10:8]
26	2A	FBDIV[7:0]
27	E6	FBDIV[15:8]
28	56	FBDIV[23:16]
29	E7	FBDIV[31:24]
30	47	FBDIV[39:32]
31	00	FBDIV[42:40]
35	77	CADC_FSGAIN[7:0]

5.6 I2C Register Write Procedure to Set Output Frequency

After the frequency setting registers (Reg 23-Reg31) are calculated, there is a procedure that must be followed involving other specific control registers for the device to properly use the new frequency setting registers. Simply writing Reg23-Reg31 is not enough. The following procedure must be performed as shown to properly configure the Si569 for the desired output frequency. In other words, all the following register writes must be done, and **in the exact sequence shown**.

This programming sequence consists of three distinct phases.

1. Writing to specific registers to get the device ready to be updated.
2. Writing the calculated frequency (divider) settings for the desired output frequency.
3. Writing to specific registers necessary to start-up the device after divider registers have been updated. The new output frequency will appear on output.

The divider values shown in the table below are for the previously described Si569 example for an output frequency of 156.75 MHz (for other frequencies, replace the divider values in registers 23-31 with values specific to your frequency requirements).

Table 5.7. Si569 Register Write Sequence to Set Output Frequency

Register (decimal)	Write Data (hex)	Description	Purpose
255	0x00	Set page register to point to page 0	Get Device Ready for Update
69	0x00	Disable FCAL override (to allow FCAL for this Freq Update)	
17	0x00	Synchronously disable output	
23	0x46	HSDIV[7:0]	Update Dividers
24	0x00	LSDIV[2:0]:HSDIV[10:8]	
26	0x2A	FBDIV[7:0]	
27	0xE6	FBDIV[15:8]	
28	0x56	FBDIV[23:16]	
29	0xE7	FBDIV[31:24]	
30	0x47	FBDIV[39:32]	
31	0x00	FBDIV[42:40]	
35	0x77	CADC_FSGAIN[7:0]	Update Kv Gain
7	0x08	Start FCAL using new divider values	Startup Device
17	0x01	Synchronously enable output	

Note: Refer to the device data sheet for default Si569 I2C address or to the device data sheet addendum for your specific I2C address.

5.7 Digitally Controlled Oscillator – ADPLL: Small, Fast Frequency Changes

The Si569 can make small, fast frequency adjustments over a range of +/- 950 ppm (parts-per-million) around the device output frequency (set as described in previous sections). This mode is typically used in applications requiring a digitally controlled oscillator (DCO) for digital PLL or other types of frequency control loops. We refer to this type of application as an all-digital PLL or ADPLL.

The ADPLL mode uses a single 24 bit register, ADPLL_DELTA_M[23:0], to add an offset to the VCO frequency to affect the small frequency change. This offset is added in a synchronous fashion to prevent frequency discontinuities and can be updated as fast as the max I2C bus speed of 1 MHz will allow. The frequency offset can be positive or negative over a range of -950 ppm to +950 ppm with 0.0001164 ppm resolution.

The equation for this frequency change is simply,

$$\text{ADPLL_DELTA_M}[23:0] = \Delta \text{FoutPPM} / 0.0001164$$

Where $\Delta \text{FoutPPM}$ is the desired ppm change in output frequency, ADPLL_DELTA_M[23:0] is a two's complement 24 bit value, and 0.0001164 is a constant per-bit ppm value. The 24 bit ADPLL_DELTA_M[23:0] value is written into three sequential 8 bit registers in LSByte to MSByte order via I2C. Upon writing the MSByte, the frequency change takes effect. Below is an example VB to implement this feature. (Note that writing ADPLL_DELTA_M[23:0] = 0x000 will result in no frequency offset and return to the nominal output frequency.)

VB Code example for ADPLL (small frequency change) calculation and operation:

```
nAddr = Device I2C address
PPM_Delta = desired PPM frequency shift

Function Set_ADPLL(ByVal nAddr As UInteger, ByVal PPM_Delta As Double) As Integer
    Dim ADPLL_PPM_StepSize As Double = 0.0001164
    Dim ADPLL_Delta_M As Integer
    Dim Reg231 As UInteger = 0
    Dim Reg232 As UInteger = 0
    Dim Reg233 As UInteger = 0
    Dim ReturnCode As Integer = 0 '1=OK, -1 PPM requested is out of bounds
    If (PPM_Delta <= 950 And PPM_Delta >= -950) Then
        ADPLL_Delta_M = (PPM_Delta / ADPLL_PPM_StepSize)
        Reg231 = (ADPLL_Delta_M And &HFF)
        Reg232 = (ADPLL_Delta_M >> 8) And &HFF
        Reg233 = (ADPLL_Delta_M >> 16) And &HFF
        I2C_Write(nAddr, 0, 231, Reg231) 'write "Reg231" value to register 231 at nAddr, page 0 (LSByte)
        I2C_Write(nAddr, 0, 232, Reg232) 'write "Reg232" value to register 232 at nAddr, page 0
        I2C_Write(nAddr, 0, 233, Reg233) 'write "Reg233" value to register 233 at nAddr, page 0
    (MSByte)
        ReturnCode = 1
    Else
        ReturnCode = -1
    End If
    Return (ReturnCode)
End Function
```

5.8 Configuring High Drive LVDS Swing

The Si569 LVDS clock output swing can be increased 100 mV via I2C to have the same swing as AC-coupled CML. This is done by programming the three registers as shown in the table below.

Table 5.8. LVDS and CML Output Drive Settings

Register Address (dec)	Output Drive	LVDS (dec)	High Drive LVDS / CML (dec)
16 [5:0]	OD_DRV_TRIM_V3P3[5:0]	17	20
125 [5:0]	OD_DRV_TRIM_V2P5[5:0]	20	23
126 [5:0]	OD_DRV_TRIM_V1P8[5:0]	22	25

5.9 Register Map Reference

Table 5.9. Register Map Reference Summary

Register (decimal)	Register Bit								Type	Reset Value

Table 5.10. Register Bit Field Summary

Register Bit Field Name	Bit Field (#bits)	Register	Description
RESET	1	7	Set to 1 to reset device. Self clearing.
MS_ICAL2	1	7	Set to 1 to initiate FCAL. Self clearing.
HSDIV[10:0]	11	23-24	HSDIV is High-speed output divider value in unsigned 11-bit binary format. Valid divide values are from 5 to 2046, with values of 5-33 even or odd, and values 34-2046 restricted to even values only.
LSDIV[2:0]	3	24	LSDIV sets a power-of-2 output divider. Values of 0,1,2,3,4,5,6,7 result in divide ratio of 1,2,4,8,16,32,32,32 respectively. Note that a value of 0 (divide-by-1) essentially bypasses this divider.

Register Bit Field Name	Bit Field (#bits)	Register	Description
FBDIV[42:0]	43	26-31	The main DSPLL system feedback divide (FBDIV) value for Si56x. This 43 bit value is composed of an unsigned 11-bit integer value (FBDIV[42:32]) concatenated with a 32-bit fractional value (FBDIV[31:0]), for an 11.32 fixed point binary format. The valid range of the 11-bit integer part is from 60 to 2045.
KV_VCXO[4:0]	5	32	Sets Vc voltage control gain Kv (ppm/V). Multiply the register value in decimal by 7.5 to get the actual Kv in ppm/V.
CADC_FSGAIN[7:0]	8	35	Full-scale Kv gain parameter. Used to set the (ppm/V) full-scale of the Vc input depending on the programmed VCO frequency.
FCAL_OVR	1	69	FCAL Override: If set to 1, FCAL is bypassed. Clear to 0 to allow FCAL.
ADPLL_DELTA_M[23:0]	24	231-233	Digital word to effect small frequency shifts to base frequency. Value is 24 bit 2's complement causing a 0.0001164 ppm per bit shift in frequency. Positive values = positive freq shift, negative values = negative freq shift. Valid range is -8161513 to +8161512, representing a max PPM shift range of -950 ppm to +950 ppm, with 0 value representing 0 PPM shift. Writing a new ADPLL_DELTA_M value will take effect upon writing to the MSByte (Register 233). Therefore, value updates should follow the sequence of writing in register order Reg 231...Reg 232...Reg 233.
PAGE[1:0]	2	255	Sets which page of registers the I2C port is reading/writing. The size of a page is 256 bytes which is the addressable range of an I2C " set address " command. The value of PAGE is multiplied by 256 and added to what " set address " has set. Physically, the 2 PAGE bits become bits [9:8] of the device's internal register map address. This mechanism allows for more than 256 registers to be addressed within the 8 bit I2C " set address " limitation.

5.12 I2C Interface

Configuration and operation of the Si569 is controlled by reading and writing to the RAM space using the I2C interface. The device operates in slave mode with 7-bit addressing and can operate in Standard-Mode (100 kbps), Fast-Mode (400 kbps), or Fast-Mode Plus (1 Mbps). Burst data transfer with auto address increments are also supported.

The I2C bus consists of a bidirectional serial data line (SDA) and a serial clock input (SCL). Both the SDA and SCL pins must be connected to the VDD supply via an external pull-up as recommended by the I2C specification. The Si569 7-bit I2C slave address is user-customized during the part number configuration process.

Data is transferred MSB first in 8-bit words as specified by the I2C specification. A write command consists of a 7-bit device (slave) address + a write bit, an 8-bit register address, and 8 bits of data as shown in the figure below.

A write burst operation is also shown where every additional data word is written using an auto-incremented address.

Write Operation – Single Byte

Write Operation - Burst (Auto Address Increment)

Figure 5.3. I2C Write Operation

A read operation is performed in two stages. A data write is used to set the register address, then a data read is performed to retrieve the data from the set address. A read burst operation is also supported. This is shown in the figure below.

Read Operation – Single Byte

Read Operation - Burst (Auto Address Increment)

Figure 5.4. I2C Read Operation

The timing specifications and timing diagram for the I2C bus is compatible with the I2C-Bus standard. SDA timeout is supported for compatibility with SMBus interfaces.

The I2C bus can be operated at a bus voltage of 1.71 to 3.63 V and should be the same voltage as the Si569 VDD.

6.2 Package Outline (3.2x5 mm)

The figure below illustrates the package details for the 5x3.2 mm Si569. The table below lists the values for the dimensions shown in the illustration.

Figure 6.2. Si569 (3.2x5 mm) Outline Diagram

Table 6.2. Package Diagram Dimensions (mm)

Dimension	MIN	NOM	MAX	Dimension	MIN	NOM	MAX
A	1.02	1.17	1.33	E1	2.85 BSC		
A2	0.50	0.55	0.60	L	0.8	0.9	1.0
A3	0.45	0.50	0.55	L1	0.45	0.55	0.65
b	0.54	0.64	0.74	L2	0.05	0.10	0.15
b1	0.54	0.64	0.75	L3	0.15	0.20	0.25
D	5.00 BSC			aaa	0.15		
D1	4.65 BSC			bbb	0.15		
e	1.27 BSC			ccc	0.08		
e1	1.625 TYP			ddd	0.10		
E	3.20 BSC			eee	0.05		

Notes:

1. All dimensions shown are in millimeters (mm) unless otherwise noted.
2. Dimensioning and Tolerancing per ANSI Y14.5M-1994.

7. PCB Land Pattern

7.1 PCB Land Pattern (5x7 mm)

The figure below illustrates the 5x7 mm PCB land pattern for the Si569. The table below lists the values for the dimensions shown in the illustration.

Figure 7.1. Si569 (5x7 mm) PCB Land Pattern

Table 7.1. PCB Land Pattern Dimensions (mm)

Dimension	(mm)	Dimension	(mm)
C1	4.20	Y1	1.95
C2	6.05	X2	1.80
E	2.54	Y2	0.75
X1	1.55		

Notes:

General

1. All dimensions shown are in millimeters (mm) unless otherwise noted.
2. Dimensioning and Tolerancing is per the ANSI Y14.5M-1994 specification.
3. This Land Pattern Design is based on the IPC-7351 guidelines.
4. All dimensions shown are at Maximum Material Condition (MMC). Least Material Condition (LMC) is calculated based on a Fabrication Allowance of 0.05 mm.

Solder Mask Design

1. All metal pads are to be non-solder mask defined (NSMD). Clearance between the solder mask and the metal pad is to be 60 μ m minimum, all the way around the pad.

Stencil Design

1. A stainless steel, laser-cut and electro-polished stencil with trapezoidal walls should be used to assure good solder paste release.
2. The stencil thickness should be 0.125 mm (5 mils).
3. The ratio of stencil aperture to land pad size should be 1:1.

Card Assembly

1. A No-Clean, Type-3 solder paste is recommended.
2. The recommended card reflow profile is per the JEDEC/IPC J-STD-020D specification for Small Body Components.

7.2 PCB Land Pattern (3.2x5 mm)

The figure below illustrates the 3.2x5.0 mm PCB land pattern for the Si569. The table below lists the values for the dimensions shown in the illustration.

Figure 7.2. Si569 (3.2x5 mm) PCB Land Pattern

Table 7.2. PCB Land Pattern Dimensions (mm)

Dimension	(mm)	Dimension	(mm)
C1	2.70	X2	0.90
E	1.27	Y1	1.60
E1	4.30	Y2	0.70
X1	0.74		

Notes:

General

1. All dimensions shown are in millimeters (mm) unless otherwise noted.
2. Dimensioning and Tolerancing is per the ANSI Y14.5M-1994 specification.
3. This Land Pattern Design is based on the IPC-7351 guidelines.
4. All dimensions shown are at Maximum Material Condition (MMC). Least Material Condition (LMC) is calculated based on a Fabrication Allowance of 0.05 mm.

Solder Mask Design

1. All metal pads are to be non-solder mask defined (NSMD). Clearance between the solder mask and the metal pad is to be 60 μ m minimum, all the way around the pad.

Stencil Design

1. A stainless steel, laser-cut and electro-polished stencil with trapezoidal walls should be used to assure good solder paste release.
2. The stencil thickness should be 0.125 mm (5 mils).
3. The ratio of stencil aperture to land pad size should be 1:1.

Card Assembly

1. A No-Clean, Type-3 solder paste is recommended.
2. The recommended card reflow profile is per the JEDEC/IPC J-STD-020C specification for Small Body Components.

8. Top Marking

The figure below illustrates the mark specification for the Si569. The table below lists the line information.

Figure 8.1. Mark Specification

Table 8.1. Si569 Top Mark Description

Line	Position	Description
1	1–8	"Si569", xxx = Ordering Option 1, Option 2, Option 3 (e.g. Si569AAA)
2	1	x = Frequency Range Supported as described in the 1. Ordering Guide
	2–7	6-digit custom Frequency Code as described in the 1. Ordering Guide
3	Trace Code	
	Position 1	Pin 1 orientation mark (dot)
	Position 2	Product Revision (B)
	Position 3–5	Tiny Trace Code (3 alphanumeric characters per assembly release instructions)
	Position 6–7	Year (last two digits of the year), to be assigned by assembly site (ex: 2017 = 17)
	Position 8–9	Calendar Work Week number (1–53), to be assigned by assembly site

9. Revision History

Revision 1.1

September, 2018

- Updated Electrical Specifications table to include high drive LVDS swing.
- Added section [5.8 Configuring High Drive LVDS Swing](#).

Revision 1.0

June, 2018

- Initial release.
