

### FEATURES

- Charge pump with automatic gain selection of 1×, 1.5×, and 2× for maximum efficiency**
- 92% peak efficiency**
- 9 independent and programmable LED drivers**
- Each driver is capable of 25 mA (full scale)**
- Each driver has 7 bits (128 levels) of nonlinear current settings**
- Standby mode for <math><1 \mu\text{A}</math> current consumption**
- 16 programmable fade-in and fade-out times (0.0 sec to 1.75 sec) with choice of square or cubic rates**
- Automated and customizable LED blinking**
- Unique heartbeat mode for programmable double pulse lighting effects on 4 channels (D6 to D9)**
- PWM input for implementing content adjustable brightness control (cABC)**
- I<sup>2</sup>C compatible interface for all programming**
- Dedicated reset pin and built-in power on reset (POR)**
- Short circuit, overvoltage, and overtemperature protection**
- Internal soft start to limit inrush currents**
- Input to output isolation during faults or shutdown**
- Operates down to  $V_{\text{IN}} = 2.5 \text{ V}$ , with undervoltage lockout (UVLO) at 1.9 V**
- Small lead frame chip scale package (LFCSP)**

### GENERAL DESCRIPTION

The ADP8866 combines a programmable backlight LED charge pump driver with automatic blinking functions. Nine LED drivers can be independently programmed at currents up to 25 mA. The current level, fade time, and blinking rate can be programmed once and executed autonomously on a loop. Separate fade-in and fade-out times can be set for the backlight LEDs.

### APPLICATIONS

- Mobile display backlighting
- Mobile phone keypad backlighting
- LED indication and status lights
- Automated LED blinking

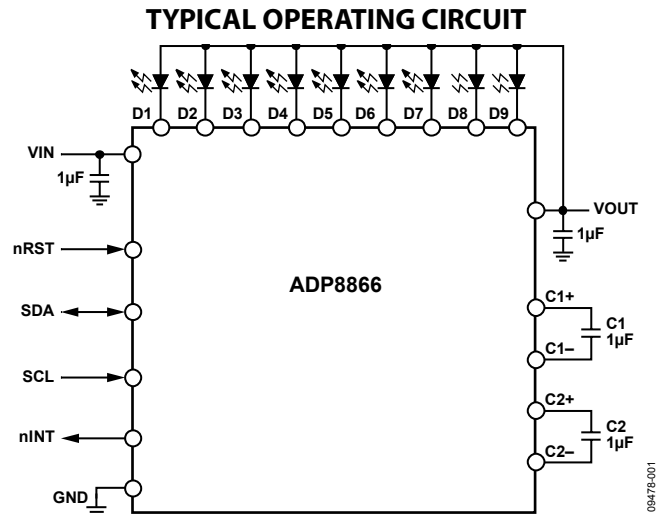

Figure 1.

Driving all of this is a two-capacitor charge pump with gains of 1×, 1.5×, and 2×. This setup is capable of driving a maximum  $I_{\text{OUT}}$  of 240 mA from a supply of 2.5 V to 5.5 V. A full suite of safety features including short-circuit, overvoltage, and over-temperature protection allows easy implementation of a safe and robust design. Additionally, input inrush currents are limited via an integrated soft start combined with controlled input to output isolation.

## ABSOLUTE MAXIMUM RATINGS

Table 2.

Parameter	Rating
VIN, VOUT to GND	−0.3 V to +6 V
D1, D2, D3, D4, D5, D6, D7, D8, and D9 to GND	−0.3 V to +6 V
nINT, nRST, SCL, and SDA to GND	−0.3 V to +6 V
Output Short-Circuit Duration	Indefinite
Operating Ambient Temperature Range	−40°C to +85°C <sup>1</sup>
Operating Junction Temperature Range	−40°C to +125°C
Storage Temperature Range	−65°C to +150°C
Soldering Conditions	JEDEC J-STD-020
ESD (Electrostatic Discharge)	
Human Body Model (HBM)	±2.0 kV
Charged Device Model (CDM)	±1.5 kV

<sup>1</sup> The maximum operating junction temperature ( $T_{J(MAX)}$ ) supersedes the maximum operating ambient temperature ( $T_{A(MAX)}$ ). See the Maximum Temperature Ranges section for more information.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

Absolute maximum ratings apply individually only, not in combination. Unless otherwise specified, all voltages are referenced to GND.

## MAXIMUM TEMPERATURE RANGES

The maximum operating junction temperature ( $T_{J(MAX)}$ ) supersedes the maximum operating ambient temperature ( $T_{A(MAX)}$ ). Therefore, in situations where the ADP8866 is exposed to poor thermal resistance and a high power dissipation ( $P_D$ ), the maximum ambient temperature may need to be derated. In these cases, the ambient temperature maximum can be calculated with the following equation:

$$T_{A(MAX)} = T_{J(MAX)} - (\theta_{JA} \times P_{D(MAX)})$$

## THERMAL RESISTANCE

The  $\theta_{JA}$  (junction to air) and  $\theta_{JC}$  (junction to case) are determined according to JESD51-9 on a 4-layer printed circuit board (PCB) with natural convection cooling. The exposed pad must be soldered to GND.

Table 3. Thermal Resistance

Package Type	$\theta_{JA}$	$\theta_{JC}$	Unit
LFCSFP	38.6	3.56	°C/W

## ESD CAUTION

### ESD (electrostatic discharge) sensitive device.

Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

Figure 3. LFCSP Pin Configuration

Table 4. Pin Function Descriptions

Pin No.	Mnemonic	Description
14	VIN	Battery Voltage 2.5 V to 5.5 V.
3	D1	LED Sink 1 Output.
2	D2	LED Sink 2 Output.
1	D3	LED Sink 3 Output.
20	D4	LED Sink 4 Output.
19	D5	LED Sink 5 Output.
18	D6	LED Sink 6 Output.
17	D7	LED Sink 7 Output.
16	D8	LED Sink 8 Output.
4	D9	LED Sink 9 Output.
13	VOUT	Charge Pump Output.
11	C1+	Charge Pump C1+.
9	C1-	Charge Pump C1-.
12	C2+	Charge Pump C2+.
10	C2-	Charge Pump C2-.
15	GND	Ground. Connect the exposed paddle to GND.
8	nINT	Processor Interrupt (Active Low). Requires an external pull-up resistor. If this pin is not used, it can be left floating. Alternatively, this pin can be set as the PWM input for implementing cABC dimming (see the PWM Dimming section).
5	nRST	Hardware Reset Input (Active Low). This bit resets the device to the default conditions. If not used, this pin must be tied above $V_{IH(MAX)}$ .
7	SDA	I <sup>2</sup> C Serial Data Input. Requires an external pull-up resistor.
6	SCL	I <sup>2</sup> C Clock Input. Requires an external pull-up resistor.

### TYPICAL PERFORMANCE CHARACTERISTICS

V<sub>IN</sub> = 3.6 V, SCL = 2.7 V, SDA = 2.7 V, nRST = 2.7 V, V<sub>D11:D9</sub> = 0.4 V, I<sub>OUT</sub> = 0 mA, C<sub>IN</sub> = 1 μF, C1 = 1 μF, C2 = 1 μF, C<sub>OUT</sub> = 1 μF, T<sub>A</sub> = 25°C, unless otherwise noted.

**POWER STAGE**

Typical white LEDs require up to 4 V to drive them. Therefore, some form of boosting is required to cover the typical Li Ion battery voltage variation. The ADP8866 accomplishes this with a high efficiency charge pump capable of producing a maximum I<sub>OUT</sub> of 240 mA over the entire input voltage range of 2.5 V to 5.5 V. Charge pumps use the basic principle that a capacitor stores charge based on the voltage applied to it, as shown in the following equation:

$$Q = C \times V \tag{1}$$

By charging the capacitors in different configurations, the charge and, therefore, the gain can be optimized to deliver the voltage required to power the LEDs. Because a fixed charging and discharging combination must be used, only certain multiples of gain are available. The ADP8866 is capable of automatically optimizing the gain (G) from 1×, 1.5×, and 2×. These gains are accomplished with two capacitors and an internal switching network.

In G = 1× mode, the switches are configured to pass VIN directly to VOUT. In this mode, several switches are connected in parallel to minimize the resistive drop from input to output. In G = 1.5× and G = 2× modes, the switches alternatively charge from the battery and discharge into the output. For G = 1.5×,

the capacitors are charged from VIN in series and are discharged to VOUT in parallel. For G = 2×, the capacitors are charged from VIN in parallel and are discharged to VOUT in parallel. In certain fault modes, the switches are opened and the output is physically isolated from the input.

**Automatic Gain Selection**

Each LED that is driven requires a current source. The voltage on this current source must be greater than a minimum headroom voltage (V<sub>HR(MIN)</sub>) in Table 1) to maintain accurate current regulation. The gain is automatically selected based on the minimum voltage (V<sub>DX</sub>) at all of the current sources. At startup, the device is placed into G = 1× mode and the output charges to VIN. If any V<sub>DX</sub> level is less than the required headroom, the gain is increased to the next step (G = 1.5×). A 100 μs delay is allowed for the output to stabilize prior to the next gain switching decision. If there remains insufficient current sink headroom, the gain is increased again to 2×. Conversely, to optimize efficiency, it is not desirable for the output voltage to be too high. Therefore, the gain reduces when the headroom voltage is too great. This point (labeled V<sub>D(MAX)</sub> in Figure 28) is internally calculated to ensure that the lower gain still results in ample headroom for all the current sinks. The entire cycle is illustrated in Figure 28.

NOTES  
1. V<sub>D(MAX)</sub> IS THE CALCULATED GAIN DOWN TRANSITION POINT.

09478-029

Figure 28. State Diagram for Automatic Gain Selection

Note that the gain selection criteria applies only to active current sources. If a current source has been deactivated through an I<sup>2</sup>C command (that is, only five LEDs are used for an application), the voltages on the deactivated current sources are ignored.

**Soft Start Feature**

At startup (either from UVLO activation or fault/standby recovery), the output is first charged by I<sub>SS</sub> (7.0 mA typical) until it reaches about 92% of V<sub>IN</sub>. This soft start feature reduces the inrush current that is otherwise present when the output capacitance is initially charged to V<sub>IN</sub>. When this point is reached, the controller enters 1× mode. If the output voltage is not sufficient, the automatic gain selection determines the optimal point as defined in the Automatic Gain Selection section.

**OPERATING MODES**

There are four different operating modes: active, standby, shutdown, and reset.

**Active Mode**

In active mode, all circuits are powered up and in a fully operational state. This mode is entered when nSTBY (in Register MDCR) is set to 1.

**Standby Mode**

Standby mode disables all circuitry except for the I<sup>2</sup>C receivers. Current consumption is reduced to less than 1 μA. This mode is entered when nSTBY is set to 0 or when the nRST pin is held

low for more than 100 μs (maximum). When standby is exited, a soft start sequence is performed.

**Shutdown Mode**

Shutdown mode disables all circuitry, including the I<sup>2</sup>C receivers. Shutdown occurs when V<sub>IN</sub> is below the undervoltage thresholds. When V<sub>IN</sub> rises above V<sub>IN(START)</sub> (2.0 V typical), all registers are reset and the part is placed into standby mode.

**Reset Mode**

In reset mode, all registers are set to their default values and the part is placed into standby. There are two ways to reset the part: power on reset (POR) and the nRST pin. POR is activated any-time that the part exits shutdown mode. After a POR sequence is complete, the part automatically enters standby mode.

After startup, the part can be reset by pulling the nRST pin low. As long as the nRST pin is low, the part is held in a standby state but no I<sup>2</sup>C commands are acknowledged (all registers are kept at their default values). After releasing the nRST pin, all registers remain at their default values, and the part remains in standby; however, the part does accept I<sup>2</sup>C commands.

The nRST pin has a 50 μs (typical) noise filter to prevent inadvertent activation of the reset function. The nRST pin must be held low for this entire time to activate reset.

The operating modes function according to the timing diagram in Figure 29.

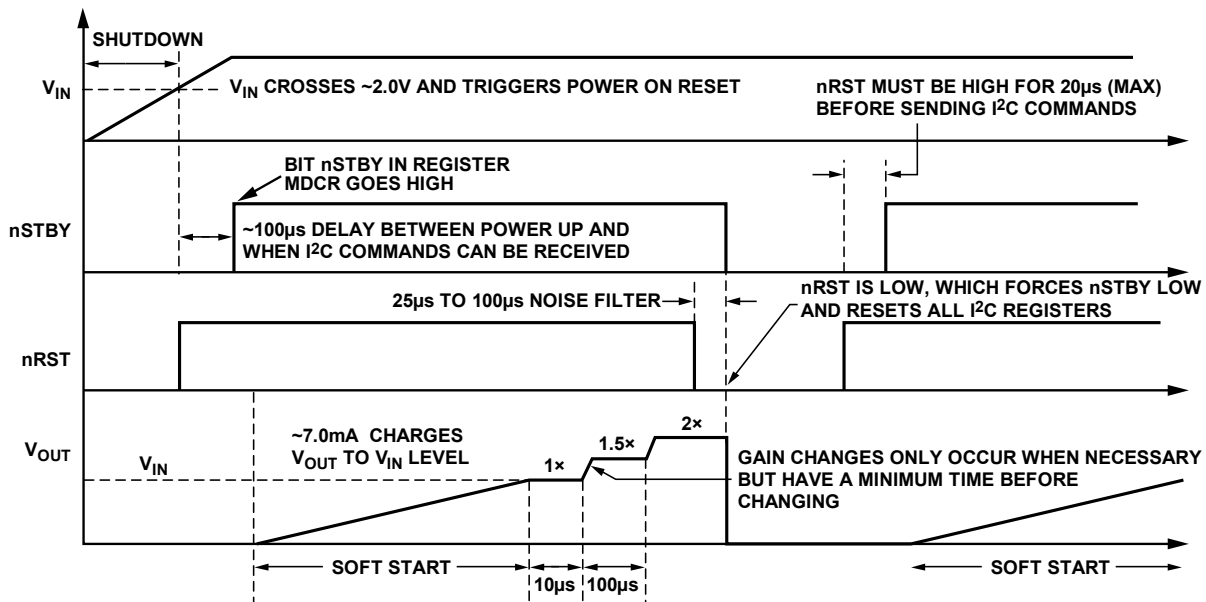

Figure 29. Typical Timing Diagram

09478-030

**LED GROUPS**

The nine LED channels can be separated into two groups: backlight (BL) and independent sinks (ISC). The group select is done in Register 0x09 and Register 0x0A, with the default being that all LEDs are part of the backlight.

Each group has its own fade-in and fade-out times (Register 0x12 for backlight and Register 0x22 for ISCs). Each group also has its own master enable located in Register 0x01. However, this master enable is overwritten if any of the SCx\_EN bits (Register 0x1A and Register 0x1B) in a group are set high. This allows complete independent control of each LED channel in both groups.

**OUTPUT CURRENT SETTINGS**

The current setting is determined by a 7-bit code programmed by the user into diode current control registers (Register 0x13 for the backlight and Register 0x23 to Register 0x2B for the independent sinks). The 7-bit resolution allows the user to set the backlight to one of 128 different levels between 0 mA and 25 mA. The ADP8866 implements a square law algorithm to achieve a nonlinear relationship between input code and backlight current. The LED output current (in milliamperes) is determined by the following equation:

$$LED\_Current(mA) = \left( Code \times \frac{\sqrt{Full - Scale Current}}{127} \right)^2 \quad (2)$$

where:

*Code* is the input code programmed by the user.

*Full-Scale Current* is the maximum sink current allowed per LED.

**OUTPUT CURRENT RANGE SELECTION**

The default maximum current range of each sink of the ADP8866 is 25.0 mA (typical). However, the ADP8866 also allows the user to select an alternative maximum current range to be applied to one or more LEDs. This alternate current range still has 128 codes for its current setting. This provides improved resolution when operating at reduced maximum currents. One of up to 60 alternate current ranges can be selected. An example of some of the available current ranges is shown below. For the complete list, see Table 23.

**Table 5. Example Current Range Options in Register 0x07**

LEVEL_SET Code	Range
000010	25.00 mA
001100	12.50 mA
010110	8.33 mA
100000	6.25 mA
101010	5.00 mA

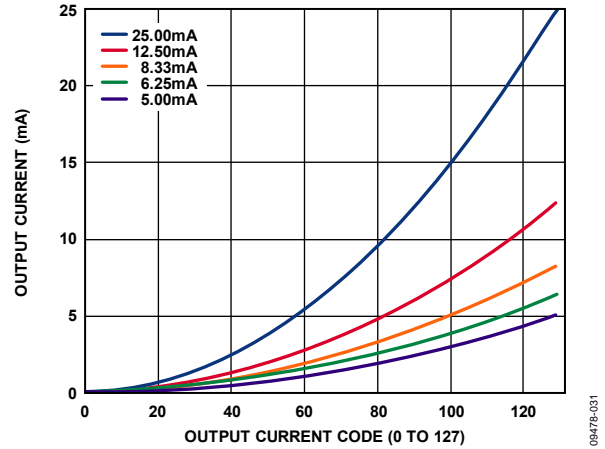

Figure 30. Output Code Effect on Various LEVEL\_SET Ranges

The LEDs that receive this alternate current range are determined by the DxLVL bits in Register 0x07 and Register 0x08.

**PWM DIMMING**

Setting the LEVEL\_SET code to 111111 (binary) allows the ADP8866 to dim its LEDs based on a PWM signal applied to the nINT pin. The LED output current is pulse width modulated with the signal applied to the nINT pin. The typical waveform and timing are shown in Figure 29. Due to the inherent delays and rise/fall times of this system, the best accuracy of the average output current is obtained with PWM frequencies below 1 kHz.

Figure 31. PWM Input Waveform and Resultant LED Current

In this mode, the nINT pin functions as an input. It no longer provides notification of the INT\_STAT register.

**AUTOMATED FADE-IN AND FADE-OUT**

The LED drivers are easily configured for automated fade-in and fade-out. Sixteen fade-in and fade-out rates can be selected via the I<sup>2</sup>C interface. Fade-in and fade-out rates range from 0.0 sec to 1.75 sec (per full-scale current). Separate fade times are assigned to the backlight LEDs and the ISC LEDs (see the LED Groups section). The BLOFF\_INT bit in Register 0x02 can be used to flag the interrupt pin when an automated backlight fade-out has occurred.

The fade profile is based on the transfer law selected (square, Cubic 10, or Cubic 11) and the delta between the actual current and the target current. Smaller changes in current reduce the fade time. For square law fades, the fade time is given by

$$\text{Fade Time} = \text{Fade Rate} \times (\text{Code}/127) \tag{4}$$

where the *Fade Rate* is shown in Table 6.

**Table 6. Available Fade-In and Fade-Out Times**

Code	Fade Rate (Seconds per 128 Codes)
0000	0.0
0001	0.05
0010	0.10
0011	0.15
0100	0.20
0101	0.25
0110	0.30
0111	0.35
1000	0.40
1001	0.45
1010	0.50
1011	0.75
1100	1.0
1101	1.25
1110	1.50
1111	1.75

The Cubic 10 and Cubic 11 laws also use the square backlight currents in Equation 3; however, the time between each step is varied to produce a steeper slope at higher currents and a shallower slope at lighter currents (see Figure 32).

Figure 32. Comparison of the Dimming Transfers Law 25 mA Scale Shown

**CABC FADE DISABLE**

The fade settings applied to the backlight in Register 0x12 are also used when the BLMX (Register 0x13) current is changed. This provides a smooth transition to new backlight current levels.

However, in some modes of operation, this feature is not desired. For example, during cABC (content adjustable

brightness control) operation, the BLMX register is updated as often as 60 times per second. And the changes to BLMX must be implemented as soon as possible. Therefore, the ADP8866 has a unique mode that allows the backlight to have very fast changes after the initial ramp in and ramp out. This mode is entered when CABCFADE in Register 0x10 is set high.

In this mode, the backlight fades in when BL\_EN and nSTBY in Register 0x01 are set high, and it fades out when BL\_EN or nSTBY is set low. However, after the fade-in is complete, any changes to the BLMX register result in near instantaneous changes to the backlight current. The situation is illustrated in Figure 33.

Figure 33. Effect of the CABCFADE Bit

**INDEPENDENT SINK CONTROL (ISC)**

Each of the nine LEDs can be configured (in Register 0x10 and Register 0x11) to operate as either part of the backlight or an independent sink current (ISC). Each ISC can be enabled independently and has its own current level. All ISCs share the same fade-in rates, fade-out rates, and fade law.

The ISCs have additional timers to facilitate blinking functions. A shared on timer (SCON), used in conjunction with the off timers of each ISC (SC1OFF, SC2OFF, SC3OFF, SC4OFF, SC5OFF, SC6OFF, and SC7OFF; see Register 0x1C through Register 0x21) allow the LED current sinks to be configured in various blinking modes. The on and off times are listed in the Register Descriptions section. Blink mode is activated by setting the off timers to any setting other than disabled.

Figure 34. LEDx Blink Mode with Fading

Program all fade-in and fade-out timers before enabling any of the LED current sinks. If ISC<sub>x</sub> is on during a blink cycle and SC<sub>x</sub>\_EN in Register 0x1B is cleared, it turns off (or fades to off if fade-out is enabled). If ISC<sub>x</sub> is off during a blink cycle and SC<sub>x</sub>\_EN is cleared, it stays off.

### ADVANCED BLINKING CONTROLS

Diode D1 to Diode D5 have basic blinking controls, while Channel D6 to Channel D9 have much more advanced capabilities. These advanced features include

- Programmable delays: Register 0x3C to Register 0x3F set the individual delays for D6 to D9. Delays are activated when the individual diode is enabled. Delay times range from 0 sec to 1.270 sec in 10 ms increments.

- Additional off time selections: D6 to D9 off times that range from 0 sec to 12.5 sec in 100 ms increments (Register 0x1E to Register 0x21). The off times can also be set to off, which turns the channel off at the completion of the blink cycle. The LED turns on again when the enable signal is toggled.
- Heartbeat mode: This mode allows a double pulse to be issued in a fully automated and customizable loop. Register 0x2C through Register 0x35 control the heartbeat effect. Up to four channels (D6 to D9) can be configured to operate in the heartbeat mode. The approximate shape of the heartbeat is shown in Figure 35:

Figure 35. Customizable Heartbeat Pulse

### SHORT-CIRCUIT PROTECTION (SCP) MODE

The ADP8866 can protect against short circuits on the output ( $V_{OUT}$ ). Short-circuit protection (SCP) is activated at the point when  $V_{OUT} < 55\%$  of  $V_{IN}$ . Note that this SCP sensing is disabled during startup and restart attempts (fault recovery). SCP sensing is reenabled 4 ms (typical) after activation. During a short-circuit fault, the device enters a low current consumption state and an interrupt flag is set. The device can be restarted at any time after receiving a short-circuit fault by simply rewriting  $nSTBY = 1$  in Register 0x01. It then repeats another complete soft start sequence. Note that the value of the output capacitance ( $C_{OUT}$ ) should be small enough to allow  $V_{OUT}$  to reach approximately 55% (typical) of  $V_{IN}$  within the 4 ms (typical) time. If  $C_{OUT}$  is too large, the device inadvertently enters short-circuit protection.

### OVERVOLTAGE PROTECTION (OVP)

Overvoltage protection is implemented on the VOUT pin. There are two types of overvoltage events: normal (no fault) and abnormal.

#### **Normal (No Fault) Overvoltage**

In this case, the VOUT pin voltage approaches  $V_{OUT(REG)}$  (4.9 V typical) during normal operation. This is not caused by a fault or load change but is simply a consequence of the input voltage times the gain reaching the clamped output voltage  $V_{OUT(REG)}$ . To prevent this, the ADP8866 detects when the output voltage rises to  $V_{OUT(REG)}$ . It then increases the effective  $R_{OUT}$  of the gain stage to reduce the voltage that is delivered. This effectively regulates  $V_{OUT}$  to  $V_{OUT(REG)}$ ; however, there is a limit to the effect that this system can have on regulating  $V_{OUT}$ . It is designed only for normal operation and is not intended to protect against faults or sudden load changes. During this mode, no interrupt is set, and the operation is transparent to the LEDs and overall application.

The automatic gain selection equations take into account the additional drop within  $R_{OUT}$  to maintain optimum efficiency.

#### **Abnormal (Fault/Sudden Load Change) Overvoltage**

Because of the open loop behavior of the charge pump, as well as how the gain transitions are computed, a sudden load change or fault can abnormally force  $V_{OUT}$  beyond 6 V. If the event happens slowly enough, the system first tries to regulate the output to 4.9 V as in a normal overvoltage scenario. However, if this is not sufficient, or if the event happens too quickly, the ADP8866 enters overvoltage protection mode when  $V_{OUT}$  exceeds the OVP threshold (typically 5.7 V). In this mode, only the charge pump is disabled to prevent  $V_{OUT}$  from rising too high. The current sources and all other device functionality remain intact. When the output voltage falls by about 500 mV (to 5.2 V typical), the charge pump resumes operation. If the fault or load step recurs, the process may repeat. An interrupt flag is set at each OVP instance.

### THERMAL SHUTDOWN (TSD)/OVERTEMPERATURE PROTECTION

If the die temperature of the ADP8866 rises above a safety limit (150°C typical), the controllers enter TSD protection mode. In this mode, most of the internal functions are shut down, the part enters standby, and the TSD\_INT interrupt is set (see Register 0x02). When the die temperature decreases below ~130°C, the part is allowed to be restarted. To restart the part, simply remove it from standby. No interrupt is generated when the die temperature falls below 130°C. However, if the software clears the pending TSD\_INT interrupt and the temperature remains above 130°C, another interrupt is generated.

The complete state machine for these faults (SCP, OVP, and TSD) is shown in Figure 36.

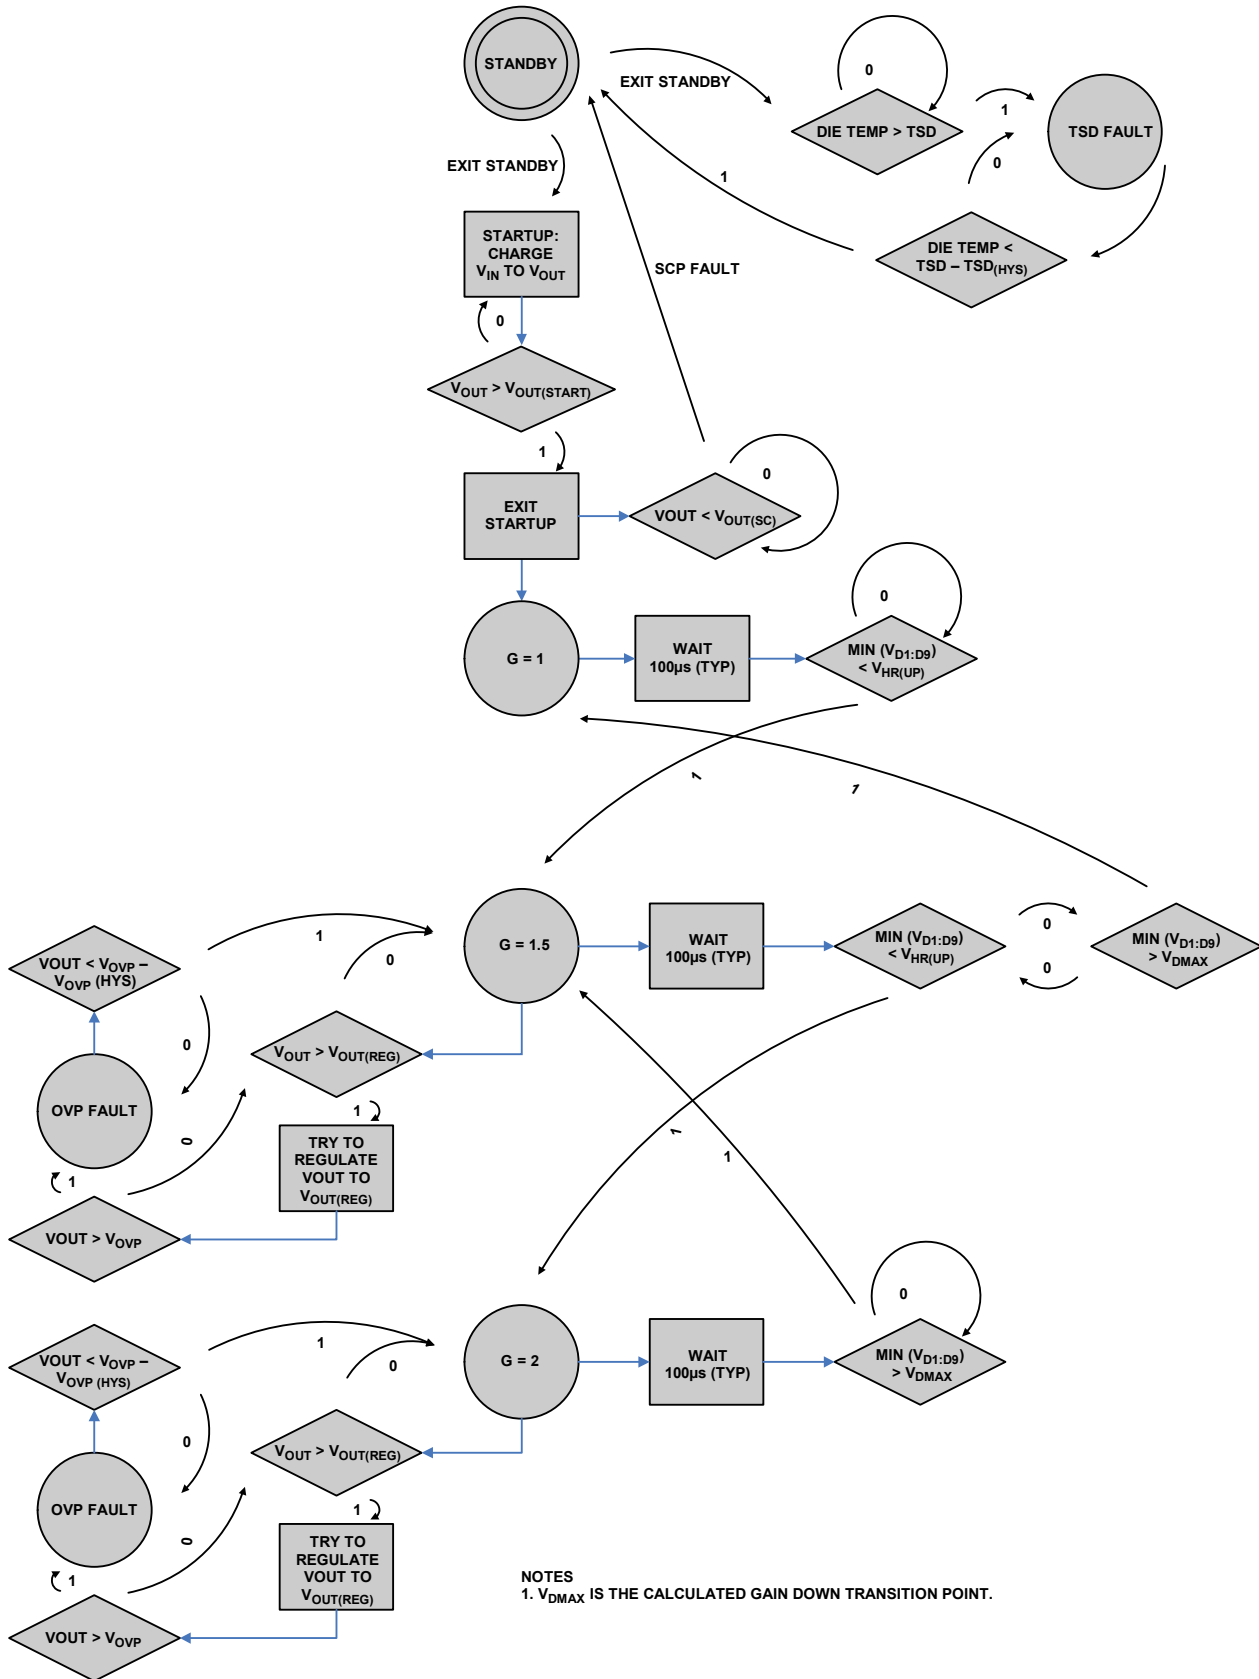

Figure 36. Fault State Machine

**INTERRUPTS**

There are four interrupt sources available on the ADP8866.

- Independent sink off: when all independent sinks that are assigned with the DxOFFINT bits high in Register 0x04 and Register 0x05 have faded to off, this interrupt (ISCOFF\_INT, Register 0x02) is set.
- Backlight off: at the end of each automated backlight fade-out, this interrupt (BLOFF\_INT, Register 0x02) is set.
- Overvoltage protection: OVP\_INT (see Register 0x02) is generated when the output voltage exceeds 5.7 V (typical).
- Thermal shutdown circuit: an interrupt (TSD\_INT, Register 0x02) is generated when entering overtemperature protection.
- Short-circuit detection: SHORT\_INT (see Register 0x02) is generated when the device enters short-circuit protection mode.

The interrupt (if any) that appears on the nINT pin is determined by the bits mapped in Register INT\_EN, 0x03. To clear an interrupt, write a 1 to the interrupt in the INT\_STAT register, 0x02, or reset the part.

**BACKLIGHT OFF INTERRUPT**

The backlight off interrupt (BLOFF\_INT) is set when the backlight completes a fade-out. This feature is useful to synchronize the backlight turn off with the LCD display driver.

Figure 37. Backlight Off Interrupt Timing Diagram

**INDEPENDENT SINK OFF INTERRUPT**

The independent sink off interrupt (ISCOFF\_INT) is generated when all the independent sinks assigned in Register 0x04 and Register 0x05 have faded to off. This can happen during a blinking profile (where SCxOFF does not equal disabled) or when an ISC is disabled. Note that even with fade-out set to 0, an ISCOFF\_INT is still set.

Figure 38. Independent Sink Off Interrupt Timing Diagram

## APPLICATIONS INFORMATION

The ADP8866 allows the charge pump to operate efficiently with a minimum of external components. Specifically, the user must select an input capacitor ( $C_{IN}$ ), output capacitor ( $C_{OUT}$ ), and two charge pump fly capacitors ( $C1$  and  $C2$ ).  $C_{IN}$  should be  $1\ \mu\text{F}$  or greater. The value must be high enough to produce a stable input voltage signal at the minimum input voltage and maximum output load. A  $1\ \mu\text{F}$  capacitor for  $C_{OUT}$  is recommended. Larger values are permissible, but care must be exercised to ensure that  $V_{OUT}$  charges above 55% (typical) of  $V_{IN}$  within 4 ms (typical). See the Short-Circuit Protection (SCP) Mode section for more detail.

For best practice, it is recommended that the two charge pump fly capacitors be  $1\ \mu\text{F}$ ; larger values are not recommended and smaller values may reduce the ability of the charge pump to deliver maximum current. For optimal efficiency, the charge pump fly capacitors should have low equivalent series resistance (ESR). Low ESR X5R or X7R capacitors are recommended for all four components. Minimum voltage ratings should adhere to the guidelines in Table 7:

**Table 7. Capacitor Stress in Each Charge Pump Gain State**

Capacitor	Gain = 1x	Gain = 1.5x	Gain = 2x
$C_{IN}$ (Input Capacitor)	$V_{IN}$	$V_{IN}$	$V_{IN}$
$C_{OUT}$ (Output Capacitor)	$V_{IN}$	$V_{IN} \times 1.5$ (Max of 5.5 V)	$V_{IN} \times 2.0$ (Max of 5.5 V)
$C1$ (Charge Pump Capacitor)	None	$V_{IN} \div 2$	$V_{IN}$
$C2$ (Charge Pump Capacitor)	None	$V_{IN} \div 2$	$V_{IN}$

Any color LED can be used provided that the  $V_f$  (forward voltage) is less than 4.3 V. However, using lower  $V_f$  LEDs reduces the input power consumption by allowing the charge pump to operate at lower gain states.

The equivalent model for a charge pump is shown in Figure 39.

Figure 39. Charge Pump Equivalent Circuit Model

The input voltage is multiplied by the gain ( $G$ ) and delivered to the output through an effective charge pump resistance ( $R_{OUT}$ ). The output current flows through  $R_{OUT}$  and produces an  $IR$  drop, which yields

$$V_{OUT} = G \times V_{IN} - I_{OUT} \times R_{OUT}(G) \quad (6)$$

The  $R_{OUT}$  term is a combination of the  $R_{DS(ON)}$  resistance for the switches used in the charge pump and a small resistance that accounts for the effective dynamic charge pump resistance. The  $R_{OUT}$  level changes based upon the gain (the configuration of the

switches). Typical  $R_{OUT}$  values are given in Table 1 and Figure 14 and Figure 16.

$V_{OUT}$  is also equal to the largest  $V_f$  of the LEDs used plus the voltage drop across the regulating current source. This gives

$$V_{OUT} = V_{f(MAX)} + V_{DX} \quad (7)$$

Combining Equation 6 and Equation 7 gives

$$V_{IN} = (V_{f(MAX)} + V_{DX} + I_{OUT} \times R_{OUT}(G))/G \quad (8)$$

This equation is useful for calculating approximate bounds for the charge pump design.

### Determining the Transition Point of the Charge Pump

Consider the following design example where:

$$V_{f(MAX)} = 3.7\ \text{V}$$

$$I_{OUT} = 140\ \text{mA} \text{ (7 LEDs at 20 mA each)}$$

$$R_{OUT}(G = 1.5\times) = 3\ \Omega \text{ (obtained from Figure 12)}$$

At the point of a gain transition,  $V_{DX} = V_{HR(UP)}$ . Table 1 gives the typical value of  $V_{HR(UP)}$  as 0.2 V. Therefore, the input voltage level when the gain transitions from 1.5x to 2x is

$$V_{IN} = (3.7\ \text{V} + 0.2\ \text{V} + 140\ \text{mA} \times 3\ \Omega)/1.5 = 2.88\ \text{V}$$

### LAYOUT GUIDELINES

- For optimal noise immunity, place the  $C_{IN}$  and  $C_{OUT}$  capacitors as close to their respective pins as possible. These capacitors should share a short ground trace. If the LEDs are a significant distance from the  $V_{OUT}$  pin, another capacitor on  $V_{OUT}$ , placed closer to the LEDs, is advisable.
- For optimal efficiency, place the charge pump fly capacitors as close to the part as possible.
- The ground pin should be connected at the ground for the input and output capacitors. The LFCSP exposed pad must be soldered at the board to the GND pin.
- Unused diode pins [D1:D9] can be connected to ground or  $V_{OUT}$  or remain floating. However, the unused diode current sinks must be removed from the charge pump gain calculation by setting the appropriate  $DxPWR$  bits high in Register 0x09 and Register 0x0A.
- If the interrupt pin ( $nINT$ ) is not used, connect it to ground or leave it floating. Never connect it to a voltage supply, except through a  $\geq 1\ \text{k}\Omega$  series resistor.
- The ADP8866 has an integrated noise filter on the  $nRST$  pin. Under normal conditions, it is not necessary to filter the reset line. However, if exposed to an unusually noisy signal, it is beneficial to add a small RC filter or bypass capacitor on this pin. If the  $nRST$  pin is not used, it must be pulled well above the  $V_{IH(MAX)}$  level (see Table 1). Do not allow the  $nRST$  pin to float.

## I<sup>2</sup>C PROGRAMMING AND DIGITAL CONTROL

The ADP8866 provides full software programmability to facilitate its adoption in various product architectures. The I<sup>2</sup>C address is 0100111x (x = 0 during write, x = 1 during read). Therefore, the write address is 0x4E, and the read address is 0x4F.

Notes on the general behavior of registers:

- All registers are set to default values on reset or in case of a UVLO event.

- All registers are read/write unless otherwise specified
- Unused bits are read-as-zero.

Table 8 through Table 103 provide register and bit descriptions. The reset value for all bits in the bit map tables is all 0s, except in Table 9 (see Table 9 for its unique reset value). Wherever the acronym N/A appears in the tables, it means not applicable.

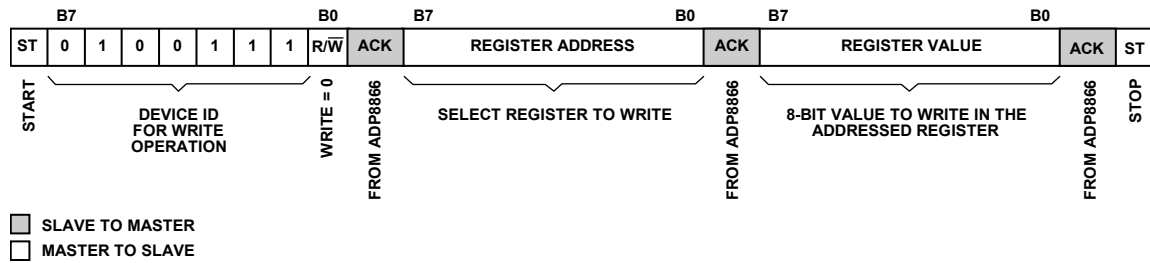

Figure 40. I<sup>2</sup>C Write Sequence

**Table 11.**

Bit Name	Bit No.	Description
N/A	7	Reserved.
INT_CFG	6	Interrupt configuration. 1 = processor interrupt deasserts for 50 $\mu$ s and reasserts with pending events. 0 = processor interrupt remains asserted if the host tries to clear the interrupt while there is a pending event.
NSTBY	5	1 = device is in normal mode. 0 = device is in standby, only I <sup>2</sup> C is enabled.
ALT_GSEL	4	1 = charge pump gain is automatically set to 1 $\times$ every time that the BLMX (Register 0x13) is written to. 0 = writing to BLMX (Register 13) has no unique effect on the charge pump gain.
GDWN_DIS	3	1 = the charge pump does not switch down in gain until all LEDs are off. The charge pump switches up in gain as needed. This feature is useful if the <a href="#">ADP8866</a> charge pump is used to drive an external load. 0 = the charge pump automatically switches up and down in gain. This provides optimal efficiency but is not suitable for driving external loads (other than those connected to the <a href="#">ADP8866</a> diode drivers).
SIS_EN	2	Master enable for independent sinks. 1 = enables all LED current sinks designated as independent sinks. This bit has no effect if any of the SCx_EN bits that are part of the independent sinks group in Register 0x1A and Register 0x1B are set. 0 = disables all sinks designated as independent sinks. This bit has no effect if any of the SCx_EN bits that are part of the independent sinks group in Register 0x1A and Register 0x1B are set.
N/A	1	Reserved.
BL_EN	0	Master enable for backlight sinks. 1 = enables all LED current sinks designated as backlight. 0 = disables all sinks designated as backlight.

**Interrupt Status Register (INT\_STAT)—Register 0x02**

Table 12. INT\_STAT Bit Map

Table 26.

Bit Name	Bit No.	Description
D8LVL	7	Diode 8 level select. 1 = control with the LEVEL_SET bits. 0 = normal mode (25 mA full-scale current).
D7LVL	6	Diode 7 level select. 1 = control with the LEVEL_SET bits. 0 = normal mode (25 mA full-scale current).
D6LVL	5	Diode 6 level select. 1 = control with the LEVEL_SET bits. 0 = normal mode (25 mA full-scale current).

Bit Name	Bit No.	Description
D5LVL	4	Diode 5 level select. 1 = control with the LEVEL_SET bits. 0 = normal mode (25 mA full-scale current).
D4LVL	3	Diode 4 level select. 1 = control with the LEVEL_SET bits. 0 = normal mode (25 mA full-scale current).
D3LVL	2	Diode 3 level select. 1 = control with the LEVEL_SET bits. 0 = normal mode (25 mA full-scale current).
D2LVL	1	Diode 2 level select. 1 = control with the LEVEL_SET bits. 0 = normal mode (25 mA full-scale current).
D1LVL	0	Diode 1 level select. 1 = control with the LEVEL_SET bits. 0 = normal mode (25 mA full-scale current).

### LED Power Source Selection 1 (PWR\_SEL1)—Register 0x09

Table 27. PWR\_SEL1 Bit Map

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Reserved							D9PWR

Table 28.

Bit Name	Bit No.	Description
N/A	[7:1]	Reserved.
D9PWR	0	Diode 9 LED power source select. 1 = the LED is powered from the battery or other power source. 0 = the LED is powered from the charge pump.

### LED Power Source Selection 2 (PWR\_SEL2)—Register 0x0A

Table 29. PWR\_SEL2 Bit Map

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
D8PWR	D7PWR	D6PWR	D5PWR	D4PWR	D3PWR	D2PWR	D1PWR

Table 30.

Bit Name	Bit No.	Description
D8PWR	7	Diode 8 LED power source select. 1 = the LED is powered from the battery or other power source. 0 = the LED is powered from the charge pump.
D7PWR	6	Diode 7 LED power source select. 1 = the LED is powered from the battery or other power source. 0 = the LED is powered from the charge pump.
D6PWR	5	Diode 6 LED power source select. 1 = the LED is powered from the battery or other power source. 0 = the LED is powered from the charge pump.
D5PWR	4	Diode 5 LED power source select. 1 = the LED is powered from the battery or other power source. 0 = the LED is powered from the charge pump.
D4PWR	3	Diode 4 LED power source select. 1 = the LED is powered from the battery or other power source. 0 = the LED is powered from the charge pump.

Bit Name	Bit No.	Description
D3PWR	2	Diode 3 LED power source select. 1 = the LED is powered from the battery or other power source. 0 = the LED is powered from the charge pump.
D2PWR	1	Diode 2 LED power source select. 1 = the LED is powered from the battery or other power source. 0 = the LED is powered from the charge pump.
D1PWR	0	Diode 1 LED power source select. 1 = the LED is powered from the battery or other power source. 0 = the LED is powered from the charge pump.

## BACKLIGHT REGISTER DESCRIPTIONS

### Configuration Register (CFGR)—Register 0x10

Table 31. CFGR Bit Map

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
Reserved			D9SEL	CABCFADE	BL_LAW		Reserved

Table 32.

Bit Name	Bit No.	Description
N/A	[7:5]	Reserved.
D9SEL	4	Diode 9 backlight select. 1 = selects LED9 as part of the independent sinks group. 0 = selects LED9 as part of the backlight group.
CABCFADE	3	Selects how the backlight current responds to changes in its I <sup>2</sup> C setpoint after the backlight is enabled and the fade-in is complete. 1 = any changes to the backlight current setting (Register 0x13) result in a near instant transition to the new current level. This is useful when rapid changes to the backlight current are required, such as during cABC control. 0 = any changes to the backlight current setting (Register 0x13) result in a fade to the new current level. The fade time is determined by the fade rate (set in Register 0x12) and the delta between the old and new current level.
BL_LAW	[2:1]	Backlight transfer law. 00 = square law DAC, linear time steps. 01 = square law DAC, linear time steps. 10 = square law DAC, nonlinear time steps (Cubic 10). 11 = square law DAC, nonlinear time steps (Cubic 11).
N/A	0	Reserved.

### Backlight Select (BLSEL)—Register 0x11

Table 33. BLSEL Bit Map

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
D8SEL	D7SEL	D6SEL	D5SEL	D4SEL	D3SEL	D2SEL	D1SEL

Table 34.

Bit Name	Bit No.	Description
D8SEL	7	Diode 8 backlight select. 1 = selects LED8 as part of the independent sinks group. 0 = selects LED8 as part of the backlight group.
D7SEL	6	Diode 7 backlight select. 1 = selects LED7 as part of the independent sinks group. 0 = selects LED7 as part of the backlight group.
D6SEL	5	Diode 6 backlight select. 1 = selects LED6 as part of the independent sinks group. 0 = selects LED6 as part of the backlight group.

Bit Name	Bit No.	Description
D5SEL	4	Diode 5 backlight select. 1 = selects LED5 as part of the independent sinks group. 0 = selects LED5 as part of the backlight group.
D4SEL	3	Diode 4 backlight select. 1 = selects LED4 as part of the independent sinks group. 0 = selects LED4 as part of the backlight group.
D3SEL	2	Diode 3 backlight select. 1 = selects LED3 as part of the independent sinks group. 0 = selects LED3 as part of the backlight group.
D2SEL	1	Diode 2 backlight select. 1 = selects LED2 as part of the independent sinks group. 0 = selects LED2 as part of the backlight group.
D1SEL	0	Diode 1 backlight select. 1 = selects LED1 as part of the independent sinks group. 0 = selects LED1 as part of the backlight group.

### Backlight Fade (BLFR)—Register 0x12

Table 35. BLFR Bit Map

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
BL_FO				BL_FI			

Table 36.

Bit Name	Bit No.	Description
BL_FO	[7:4]	Backlight fade-out rate. The backlight fades from its current value to the off value. The times listed for BL_FO are for a full-scale fade-out. Fades between closer current values reduce the fade time. See the Automated Fade-in and Fade-Out section for more information. 0000 = 0.0 sec (fade-out disabled). 0001 = 0.05 sec. 0010 = 0.10 sec. 0011 = 0.15 sec. 0100 = 0.20 sec. 0101 = 0.25 sec. 0110 = 0.30 sec. 0111 = 0.35 sec. 1000 = 0.40 sec. 1001 = 0.45 sec. 1010 = 0.50 sec. 1011 = 0.75 sec. 1100 = 1.00 sec. 1101 = 1.25 sec. 1110 = 1.50 sec. 1111 = 1.75 sec.
BL_FI	[3:0]	Backlight fade-in rate. The backlight fades from 0 to its programmed value when the backlight is turned on. The times listed for BL_FI are for a full-scale fade-in. Fades between closer current values reduce the fade time. See the Automated Fade-in and Fade-Out section for more information. 0000 = 0.0 sec (fade-in disabled). 0001 = 0.05 sec. 0010 = 0.10 sec. 0011 = 0.15 sec. ... 1111 = 1.75 sec.

**Independent Sink Current Time (ISCT1)—Register 0x1C**

Table 44. ISCT1 Bit Map

Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0
SCON				Reserved		SC5OFF	

Table 45.

Bit Name	Bit No.	Description
SCON	[7:4]	SC on time. If the SCxOFF time is not disabled, then when the independent current sink is enabled (Register 0x1A and Register 0x1B), it remains on for the on time selected (per the following list) and then turns off. 0000 = 0.00 sec <sup>1</sup> . 0001 = 0.05 sec. 0010 = 0.10 sec. 0011 = 0.15 sec. 0100 = 0.20 sec. 0101 = 0.25 sec. 0110 = 0.30 sec. 0111 = 0.35 sec. 1000 = 0.40 sec. 1001 = 0.45 sec. 1010 = 0.50 sec. 1011 = 0.55 sec. 1100 = 0.60 sec. 1101 = 0.65 sec. 1110 = 0.70 sec. 1111 = 0.75 sec.
N/A	[3:2]	Reserved.
SC5OFF	[1:0]	SC5 off time. When the SC off time is disabled, the SC remains on while enabled. When the SC off time is set to any other value, the ISC turns off for the off time (per the following listed times) and then turns on according to the SCON setting. 00 = off time disabled <sup>2</sup> . 01 = 0.6 sec. 10 = 1.2 sec. 11 = 1.8 sec.

<sup>1</sup> If SCON is set to 0 sec, then after the ISC completes a ramp up, it immediately starts to ramp back down again (if SCxOFF is not disabled). SCON should not be set to 0 if the fade-in time is also 0 seconds.

<sup>2</sup> An independent sink remains on continuously when it is enabled and SCxOFF is disabled.

**Independent Sink Current Time (ISCT2)—Register 0x1D**

Table 46. ISCT2 Bit Map

Reserved	DELAY9						

Table 103.

Bit Name	Bit No.	Description
N/A	7	Reserved.
DELAY9	[6:0]	Enable delay time for SC9. When SC9 is enabled, the <a href="#">ADP8866</a> automatically waits the specified time before starting the SC9 fade-in. 0000 = 0 ms (no delay when SC9 enable is exercised). 0000001 = 10 ms. 0000010 = 20 ms. 0000011 = 30 ms. ... 1111111 = 1270 ms.

OUTLINE DIMENSIONS

COMPLIANT TO JEDEC STANDARDS MO-220-WGGD-11.
