Ultralow offset voltage

$T_A = 25^\circ\text{C}$, 25 μV maximum

Outstanding offset voltage drift 0.3 $\mu\text{V}/^\circ\text{C}$ maximum

Excellent open-loop gain and gain linearity

12 $\text{V}/\mu\text{V}$ typical

CMRR: 130 dB minimum

PSRR: 115 dB minimum

Low supply current 2.0 mA maximum

Fits industry-standard precision operational amplifier sockets

GENERAL DESCRIPTION

The **OP177** features one of the highest precision performance of any operational amplifier currently available. Offset voltage of the **OP177** is only 25 μV maximum at room temperature. The ultralow V_{OS} of the **OP177** combines with the exceptional offset voltage drift (TCV_{OS}) of 0.3 $\mu\text{V}/^\circ\text{C}$ maximum to eliminate the need for external V_{OS} adjustment and increases system accuracy over temperature.

The **OP177** open-loop gain of 12 $\text{V}/\mu\text{V}$ is maintained over the full $\pm 10 \text{ V}$ output range. CMRR of 130 dB minimum, PSRR of 120 dB minimum, and maximum supply current of 2 mA are just a few examples of the excellent performance of this operational amplifier. The combination of outstanding specifications of the **OP177** ensures accurate performance in high closed-loop gain applications.

PIN CONFIGURATION

8-Lead SOIC (S-Suffix)

This low noise, bipolar input operational amplifier is also a cost effective alternative to chopper-stabilized amplifiers. The **OP177** provides chopper-type performance without the usual problems of high noise, low frequency chopper spikes, large physical size, limited common-mode input voltage range, and bulky external storage capacitors.

The **OP177** is offered in the -40°C to $+85^\circ\text{C}$ extended industrial temperature ranges. This product is available in 8-lead PDIP, as well as the space saving 8-lead SOIC.

¹ For supply voltages less than ± 22 V, the absolute maximum input voltage is equal to the supply voltage.

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

THERMAL RESISTANCE

θ_{JA} is specified for worst-case mounting conditions, that is, θ_{JA} is specified for device in socket for PDIP; θ_{JA} is specified for device soldered to printed circuit board for SOIC package.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

APPLICATIONS INFORMATION

GAIN LINEARITY

The actual open-loop gain of most monolithic operational amplifiers varies at different output voltages. This nonlinearity causes errors in high closed-loop gain circuits.

It is important to know that the manufacturer's A_{VO} specification is only a part of the solution because all automated testers use endpoint testing and, therefore, show only the average gain. For example, Figure 24 shows a typical precision operational amplifier with a respectable open-loop gain of 650 V/mV. However, the gain is not constant through the output voltage range, causing nonlinear errors. An ideal operational amplifier shows a horizontal scope trace.

Figure 25 shows the OP177 output gain linearity trace with the truly impressive average A_{VO} of 12,000 V/mV. The output trace is virtually horizontal at all points, assuring extremely high gain accuracy. Analog Devices, Inc., also performs additional testing to ensure consistent high open-loop gain at various output voltages. Figure 26 is a simple open-loop gain test circuit.

THERMOCOUPLE AMPLIFIER WITH COLD-JUNCTION COMPENSATION

An example of a precision circuit is a thermocouple amplifier that must accurately amplify very low level signals without introducing linearity and offset errors to the circuit. In this circuit, an S-type thermocouple with a Seebeck coefficient of $10.3 \mu\text{V}/^\circ\text{C}$ produces 10.3 mV of output voltage at a temperature of 1000°C . The amplifier gain is set at 973.16, thus, it produces an output voltage of 10.024 V. Extended temperature ranges beyond 1500°C are accomplished by reducing the amplifier gain. The circuit uses a low cost diode to sense the temperature at the terminating junctions and, in turn, compensates for any ambient temperature change. The OP177, with the high open-loop gain plus low offset voltage and drift, combines to yield a precise temperature sensing circuit. Circuit values for other thermocouple types are listed in Table 5.

PRECISION HIGH GAIN DIFFERENTIAL AMPLIFIER

The high gain, gain linearity, CMRR, and low TCV_{OS} of the **OP177** make it possible to obtain performance not previously available in single stage, very high gain amplifier applications. See Figure 28.

For best CMR, $\frac{R1}{R2}$ must equal $\frac{R3}{R4}$

In this example, with a 10 mV differential signal, the maximum errors are listed in Table 6.

Figure 28. Precision High Gain Differential Amplifier

Table 6. High Gain Differential Amplifier Performance

TCV_{OS}	0.0003%/°C
TCI_{OS}	0.008%/°C

ISOLATING LARGE CAPACITIVE LOADS

The circuit shown in Figure 29 reduces maximum slew rate but allows driving capacitive loads of any size without instability. Because the 100 Ω resistor is inside the feedback loop, the effect on output impedance is reduced to insignificance by the high open loop gain of the **OP177**.

Figure 29. Isolating Capacitive Loads

BILATERAL CURRENT SOURCE

The current sources shown in Figure 30 supply both positive and negative currents into a grounded load.

Note that

$$Z_O = \frac{R5 \left(\frac{R4}{R2} + 1 \right)}{\frac{R5 + R4}{R2} - \frac{R3}{R1}}$$

and that for Z_O to be infinite

$$\frac{R5 + R4}{R2} \text{ must } = \frac{R3}{R1}$$

PRECISION ABSOLUTE VALUE AMPLIFIER

The high gain and low TCV_{OS} assure accurate operation with inputs from microvolts to volts. In this circuit, the signal always appears as a common-mode signal to the operational amplifiers (for details, see Figure 31).

BASIC CURRENT SOURCE

100mA CURRENT SOURCE

$$I_{OUT} = V_{IN} \frac{R3}{R1 \times R5}$$

GIVEN $R3 = R4 + R5$, $R1 = R2$

Figure 30. Bilateral Current Source

Figure 31. Precision Absolute Value Amplifier

Figure 32. Precision Positive Peak Detector

PRECISION POSITIVE PEAK DETECTOR

In Figure 32, C_H must be polystyrene, Teflon®, or polyethylene to minimize dielectric absorption and leakage. The droop rate is determined by the size of C_H and the bias current of the [AD820](#).

PRECISION THRESHOLD DETECTOR/AMPLIFIER

In Figure 33, when $V_{IN} < V_{TH}$, amplifier output swings negative, reverse biasing diode D_1 . $V_{OUT} = V_{TH}$ if $R_L = \infty$. When $V_{IN} \geq V_{TH}$, the loop closes.

$$V_{OUT} = V_{TH} + (V_{IN} - V_{TH}) \left(1 + \frac{R_F}{R_S} \right)$$

C_C is selected to smooth the response of the loop.
