

PCI-EXPRESS GEN 1, GEN 2, GEN 3, AND GEN 4 QUAD FANOUT BUFFER

Features

- PCI-Express Gen 1, Gen 2, Gen 3, and Gen 4 common clock compliant
- Supports Serial ATA (SATA) at 100 MHz
- 100–210 MHz operation
- Low power, push pull, differential output buffers
- Internal termination for maximum integration
- Dedicated output enable pin for each output
- Four PCI-Express buffered clock outputs
- Clock input spread tolerable
- Supports LVDS outputs
- I²C support with readback capabilities
- Extended temperature: –40 to 85 °C
- 3.3 V power supply
- 24-pin QFN package

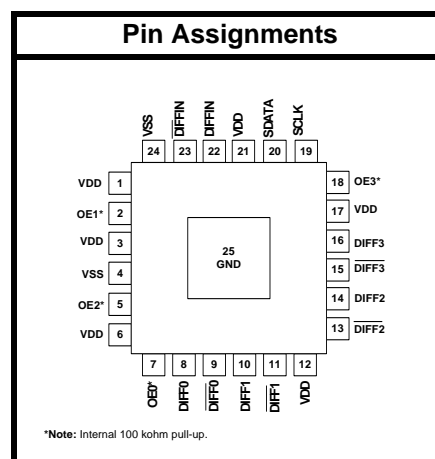

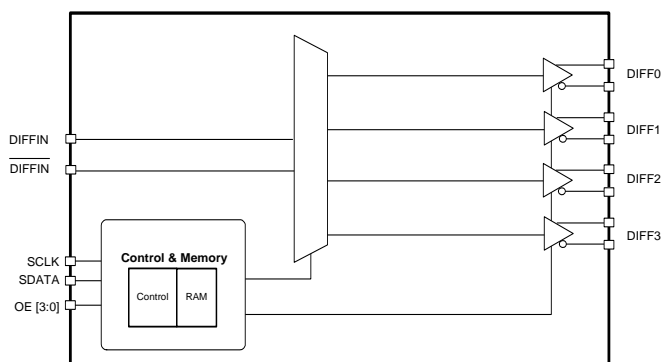

Applications

- Network attached storage
- Multi-function printers
- Wireless access point
- Routers

Description

The Si53154 is a spread spectrum tolerant PCIe clock buffer that can source four PCIe clocks simultaneously. The device has four hardware output enable control inputs for enabling the respective differential outputs on the fly. The device also features output enable control through I²C communication. I²C programmability is also available to dynamically control skew, edge rate and amplitude on the true, compliment, or both differential signals on the clock outputs. This control feature enables optimal signal integrity as well as optimal EMI signature on the clock outputs. Measuring PCIe clock jitter is quick and easy with the Silicon Labs PCIe Clock Jitter Tool. Download it for free at www.silabs.com/pcie-learningcenter.

2. Functional Description

2.1. OE Pin Definition

The OE pins are active high inputs used to enable and disable the output clocks. To enable the output clock, the OE pin needs to be logic high and the I²C output enable bit needs to be logic high. There are two methods to disable the output clocks: the OE is pulled to a logic low, or the I²C enable bit is set to a logic low. The OE pins are required to be driven at all times even though they have an internal 100 k Ω resistor.

2.2. OE Assertion

The OE signals are active high inputs used for synchronous stopping and starting the DIFF output clocks respectively while the rest of the clock generator continues to function. The assertion of the OE signal by making it logic high causes stopped respective DIFF outputs to resume normal operation. No short or stretched clock pulses are produced when the clock resumes. The maximum latency from the assertion to active outputs is no more than two to six output clock cycles.

2.3. OE Deassertion

When the OE pin is deasserted by making it logic low, the corresponding DIFF output is stopped, and the final output state is driven low.

3. Test and Measurement Setup

Figures 1–3 show the test load configuration for differential clock signals.

4. Control Registers

4.1. I²C Interface

To enhance the flexibility and function of the clock buffer, an I²C interface is provided. Through the I²C Interface, various device functions are available, such as individual clock output enable. The registers associated with the I²C Interface initialize to their default setting at power-up. The use of this interface is optional. Clock device register changes are normally made at system initialization, if any are required. Power management functions can only be programed in program mode and not in normal operation modes.

4.2. Data Protocol

The I²C protocol accepts byte write, byte read, block write, and block read operations from the controller. For block write/read operation, access the bytes in sequential order from lowest to highest (most significant bit first) with the ability to stop after any complete byte is transferred. For byte write and byte read operations, the system controller can access individually indexed bytes.

The block write and block read protocol is outlined in Table 4 while Table 5 outlines byte write and byte read protocol. The slave receiver address is 11010110 (D6h).

Notes:

General

1. All dimensions shown are in millimeters (mm).
2. This Land Pattern Design is based on the IPC-7351 guidelines.

Solder Mask Design

1. All metal pads are to be non-solder mask defined (NSMD). Clearance between the solder mask and the metal pad is to be 60 μ m minimum, all the way around the pad.

Stencil Design

1. A stainless steel, laser-cut and electro-polished stencil with trapezoidal walls should be used to assure good solder paste release.
2. The stencil thickness should be 0.125mm (5 mils).
3. The ratio of stencil aperture to land pad size should be 1:1 for all perimeter pads.
4. A 2x2 array of 1.10mm x 1.10mm openings on 1.30mm pitch should be used for the center ground pad.

Card Assembly

1. A No-Clean, Type-3 solder paste is recommended.
2. The recommended card reflow profile is per the JEDEC/IPC J-STD-020 specification for Small Body Components.
