## FEATURES

Single-supply voltage operation: 2.3 V to 5.5 V
Rail-to-rail common-mode input voltage range Low input offset voltage across $\mathrm{V}_{\mathrm{CMR}} 1 \mathrm{mV}$ typical
Guarantees comparator output logic low from $\mathrm{V}_{\mathrm{cc}}=0.9 \mathrm{~V}$ to undervoltage lockout (UVLO)
Operating temperature range: $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$
8-lead, narrow body SOIC

## APPLICATIONS

Battery management/monitoring
Power supply detection
Window comparators
Threshold detectors/discriminators
Microprocessor systems

## GENERAL DESCRIPTION

The ADCMP392 is a dual, rail-to-rail input, low power comparator ideal for use in general-purpose applications. The device operates from a single supply voltage of 2.3 V to 5.5 V and draws a minimal amount of current. The quad ADCMP392 consumes only $22.1 \mu \mathrm{~A}$ of supply current. The low voltage and low current operation of the ADCMP392 makes it ideal for battery-powered systems.

FUNCTIONAL BLOCK DIAGRAM

Figure 1.

The ADCMP392 features a common-mode input voltage range of 200 mV beyond rails, an offset voltage of 1 mV typical across the full common-mode range, and a UVLO monitor. In addition, the design of the comparator allows a defined output state upon power-up. The comparator generates a logic low output if the supply voltage is less than the UVLO threshold.
The ADCMP392 is available in a 8 -lead, narrow body SOIC package. The ADCMP392 is specified to operate over the extended temperature range of $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$.

## ABSOLUTE MAXIMUM RATINGS

Table 2.

| Parameter | Rating |
| :--- | :--- |
| VCC Pin | -0.3 V to +6 V |
| All INx+ and INx- Pins | -0.3 V to +6 V |
| All OUTx Pins | -0.3 V to +6 V |
| OUTx Pins Sink Current (Isink) | 10 mA |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Operating Temperature Range | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| Lead Temperature $(10$ sec) | $300^{\circ} \mathrm{C}$ |
| Junction Temperature | $150^{\circ} \mathrm{C}$ |

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

## THERMAL RESISTANCE

## THEORY OF OPERATION

## BASIC COMPARATOR

In its most basic configuration, a comparator can be used to convert an analog input signal to a digital output signal (see Figure 21). The analog signal on $\mathrm{INx}+$ is compared to the voltage on $\mathrm{INx}^{-}$, and the voltage at OUTx is either high or low, depending on whether $\mathrm{INx}+$ is at a higher or lower potential than $\mathrm{INx}^{-}$, respectively.

Figure 21. Basic Comparator and Input and Output Signals

## RAIL-TO-RAIL INPUT (RRI)

Using a CMOS nonRRI stage (that is, a single differential pair) limits the input voltage to approximately one gate-to-source voltage ( $\mathrm{V}_{\mathrm{GS}}$ ) away from one of the supply lines. Because $\mathrm{V}_{\mathrm{GS}}$ for normal operation is commonly more than 1 V , a single differential pair input stage comparator greatly restricts the allowable input voltage. This restriction can be quite limiting with low voltage supplies. To resolve this issue, RRI stages allow the input signal range to extend up to the supply voltage range. In the case of theADCMP392, the inputs continue to operate 200 mV beyond the supply rails.

## OPEN-DRAIN OUTPUT

The ADCMP392 has an open-drain output stage that requires an external resistor to pull up to the logic high voltage level when the output transistor is switched off. The pull-up resistor must be large enough to avoid excessive power dissipation, but small enough to switch logic levels reasonably quickly when the comparator output is connected to other digital circuitry. The rise time of the open-drain output depends on the pull-up resistor ( $\mathrm{R}_{\text {Puluup }}$ ) and load capacitor ( $\mathrm{C}_{\mathrm{L}}$ ) used.

The rise time can be calculated by

$$
\begin{equation*}
t_{R}=2.197 R_{\text {PULLUP }} C_{L} \tag{1}
\end{equation*}
$$

## POWER-UP BEHAVIOR

On power-up, when $V_{C C}$ reaches 0.9 V , the ADCMP392 is guaranteed to assert an output low logic. When the voltage on the V CC pin exceeds UVLO, the comparator inputs take control.

## CROSSOVER BIAS POINT

Rail-to-rail inputs of this type of architecture, in both op amps and comparators, have a dual front-end design. PMOS devices are inactive near the $\mathrm{V}_{\mathrm{CC}}$ rail, and NMOS devices are inactive near GND. At some predetermined point in the common-mode range, a crossover occurs. At this point, normally 0.8 V and $\mathrm{V}_{\mathrm{CC}}-0.8 \mathrm{~V}$, the measured offset voltages change.

## COMPARATOR HYSTERESIS

In noisy environments, or when the differential input amplitudes are relatively small or slow moving, adding hysteresis ( $\mathrm{V}_{\text {HYst }}$ ) to the comparator is often desirable. The transfer function for a comparator with hysteresis is shown in Figure 22. As the input voltage approaches the threshold ( 0 V in Figure 22) from below the threshold region in a positive direction, the comparator switches from low to high when the input crosses $+\mathrm{V}_{\text {HYST }} / 2$. The new switch threshold becomes $-\mathrm{V}_{\mathrm{HYST}} / 2$. The comparator remains in the high state until the $-\mathrm{V}_{\mathrm{HYST}} / 2$ threshold is crossed from below the threshold region in a negative direction. In this manner, noise or feedback output signals centered on the 0 V input cannot cause the comparator to switch states unless it exceeds the region bounded by $\pm \mathrm{V}_{\mathrm{HYst}} / 2$.

Figure 22. Comparator Hysteresis Transfer Function

## TYPICAL APPLICATIONS <br> ADDING HYSTERESIS

To add hysteresis, see Figure 23; two resistors are used to create different switching thresholds, depending on whether the input signal is increasing or decreasing in magnitude. When the input voltage increases, the threshold is above $V_{\mathrm{REF}}$, and when the input voltage decreases, the threshold is below $V_{\text {REF }}$.

Figure 23. Noninverting Comparator Configuration with Hysteresis
The upper input threshold level is given by

$$
\begin{equation*}
V_{I N \_H I}=\frac{V_{R E F}(R 1+R 2)}{R 2} \tag{2}
\end{equation*}
$$

Assuming $\mathrm{R}_{\text {LoAD }} \gg \mathrm{R} 2$, $\mathrm{R}_{\text {Pullup }}$.
The lower input threshold level is given by

$$
\begin{equation*}
V_{I N_{-} L O}=\frac{V_{\text {REF }}\left(R 1+R 2+R_{\text {PULLUP }}\right)-V_{C C} R 1}{R 2+R_{\text {PULLUP }}} \tag{3}
\end{equation*}
$$

The hysteresis is the difference between these voltages levels.

$$
\begin{equation*}
\Delta V_{I N}=\frac{V_{C C} R 1}{R 2+R_{\text {PULLUP }}} \tag{4}
\end{equation*}
$$

## WINDOW COMPARATOR FOR POSITIVE VOLTAGE MONITORING

When monitoring a positive supply, the desired nominal operating voltage for monitoring is denoted by $\mathrm{V}_{\mathrm{M}}, \mathrm{I}_{\mathrm{M}}$ is the nominal current through the resistor divider, Vov is the overvoltage trip point, and $\mathrm{V}_{\mathrm{UV}}$ is the undervoltage trip point.

Figure 24. Positive Undervoltage/Overvoltage Monitoring Configuration
Figure 24 illustrates the positive voltage monitoring input connection. Three external resistors, $\mathrm{R}_{\mathrm{x}}, \mathrm{R}_{\mathrm{Y}}$, and $\mathrm{R}_{\mathrm{Z}}$, divide the positive voltage for monitoring, $\mathrm{V}_{\mathrm{M}}$, into the high-side voltage, $\mathrm{V}_{\mathrm{PH}}$, and the low-side voltage, $\mathrm{V}_{\mathrm{PL}}$. The high-side voltage is connected to the INA+ pin and the low-side voltage is connected to the INB- pin.
To trigger an overvoltage condition, the low-side voltage (in this case, $\mathrm{V}_{\text {PL }}$ ) must exceed the $\mathrm{V}_{\text {Ref }}$ threshold on the INB+ pin. Calculate the low-side voltage, $\mathrm{V}_{\mathrm{PL}}$, by the following:

$$
\begin{equation*}
V_{P L}=V_{R E F}=V_{O V}\left(\frac{R_{Z}}{R_{X}+R_{Y}+R_{Z}}\right) \tag{5}
\end{equation*}
$$

In addition,

$$
\begin{equation*}
R_{X}+R_{Y}+R_{Z}=V_{M} / I_{M} \tag{6}
\end{equation*}
$$

Therefore, $\mathrm{R}_{\mathrm{Z}}$, which sets the desired trip point for the overvoltage monitor, is calculated as

$$
\begin{equation*}
R_{Z}=\frac{\left(V_{R E F}\right)\left(V_{M}\right)}{\left(V_{O V}\right)\left(I_{M}\right)} \tag{7}
\end{equation*}
$$

To trigger the undervoltage condition, the high-side voltage, $\mathrm{V}_{\mathrm{PH}}$, must be less than the $\mathrm{V}_{\text {ref }}$ threshold on the INA- pin. The high-side voltage, $\mathrm{V}_{\mathrm{PH}}$, is calculated by

$$
\begin{equation*}
V_{P H}=V_{R E F}=V_{U V}\left(\frac{R_{Y}+R_{Z}}{R_{X}+R_{Y}+R_{Z}}\right) \tag{8}
\end{equation*}
$$

Because $\mathrm{R}_{\mathrm{Z}}$ is already known, $\mathrm{R}_{\mathrm{Y}}$ can be expressed as

$$
\begin{equation*}
R_{Y}=\frac{\left(V_{\text {REF }}\right)\left(V_{M}\right)}{\left(V_{U V}\right)\left(I_{M}\right)}-R_{Z} \tag{9}
\end{equation*}
$$

When $\mathrm{R}_{Y}$ and $\mathrm{R}_{Z}$ are known, $\mathrm{R}_{X}$ can be calculated by

$$
\begin{equation*}
R_{X}=\left(V_{M} / I_{M}\right)-R_{Y}-R_{Z} \tag{10}
\end{equation*}
$$

If $V_{M}, I_{M}, V_{\text {oV }}$, or $V_{U V}$ changes, each step must be recalculated.

## WINDOW COMPARATOR FOR NEGATIVE VOLTAGE MONITORING

Figure 25 shows the circuit configuration for negative supply voltage monitoring. To monitor a negative voltage, a reference voltage is required to connect to the end node of the voltage divider circuit, in this case, $\mathrm{V}_{\text {REF }}$.

Figure 25. Negative Undervoltage/Overvoltage Monitoring Configuration
Equation 7, Equation 9, and Equation 10 need some minor modifications for use with negative voltage monitoring. The reference voltage, $\mathrm{V}_{\text {REF }}$, is added to the overall voltage drop; therefore, it must be subtracted from $\mathrm{V}_{\mathrm{M}}, \mathrm{V}_{\mathrm{UV}}$, and $\mathrm{V}_{\text {ov }}$ before using each of them in Equation 7, Equation 9, and Equation 10.
To monitor a negative voltage level, the resistor divider circuit divides the voltage differential level between $V_{\text {ref }}$ and the negative supply voltage into the high-side voltage, $\mathrm{V}_{\mathrm{NH}}$, and the low-side voltage, $\mathrm{V}_{\mathrm{NL}}$. The high-side voltage, $\mathrm{V}_{\mathrm{NH}}$, is connected to INA+, and the low-side voltage, $\mathrm{V}_{\mathrm{NL}}$, is connected to INB-.

To trigger an overvoltage condition, the monitored voltage must exceed the nominal voltage in terms of magnitude, and the high-side voltage (in this case, $\mathrm{V}_{\mathrm{NH}}$ ) on the INA+ pin must be more negative than ground. Calculate the high-side voltage, $\mathrm{V}_{\mathrm{NH}}$, with the following formula:

$$
\begin{equation*}
V_{N H}=G N D=\left[\left(V_{R E F}-V_{O V}\right)\left(\frac{R_{X}+R_{Y}}{R_{X}+R_{Y}+R_{Z}}\right)\right]+V_{O V} \tag{11}
\end{equation*}
$$

In addition,

$$
\begin{equation*}
R_{X}+R_{Y}+R_{Z}=\frac{\left(V_{M}-V_{R E F}\right)}{I_{M}} \tag{12}
\end{equation*}
$$

Therefore, $\mathrm{R}_{\mathrm{z}}$, which sets the desired trip point for the overvoltage monitor, is calculated by

$$
\begin{equation*}
R_{Z}=\frac{-V_{\text {REF }}\left(V_{M}-V_{\text {REF }}\right)}{I_{M}\left(V_{O V}-V_{R E F}\right)} \tag{13}
\end{equation*}
$$

To trigger an undervoltage condition, the monitored voltage must be less than the nominal voltage in terms of magnitude, and the low-side voltage (in this case, $\mathrm{V}_{\mathrm{NL}}$ ) on the INB- pin must be more positive than ground. Calculate the low-side voltage, $\mathrm{V}_{\mathrm{NL}}$, by the following:

$$
\begin{equation*}
V_{N L}=G N D=\left[\left(V_{R E F}-V_{U V}\right)\left(\frac{R_{X}}{R_{X}+R_{Y}+R_{Z}}\right)\right]+V_{U V} \tag{14}
\end{equation*}
$$

Because $\mathrm{R}_{\mathrm{Z}}$ is already known, $\mathrm{R}_{\mathrm{Y}}$ can be expressed as follows:

$$
\begin{equation*}
R_{Y}=\frac{-V_{R E F}\left(V_{M}-V_{R E F}\right)}{I_{M}\left(V_{U V}-V_{R E F}\right)}-R_{Z} \tag{15}
\end{equation*}
$$

When $\mathrm{R}_{Y}$ and $\mathrm{R}_{Z}$ are known, $\mathrm{R}_{\mathrm{X}}$ is then calculated by

$$
\begin{equation*}
R_{X}=\frac{\left(V_{M}-V_{R E F}\right)}{I_{M}}-R_{Y}-R_{Z} \tag{16}
\end{equation*}
$$

## PROGRAMMABLE SEQUENCING CONTROL CIRCUIT

The circuit shown in Figure 26 is used to control the power supply sequencing. The delay is set by the combination of the pullup resistor ( Reuliup ), the load capacitor ( $\mathrm{C}_{\mathrm{L}}$ ), and the resistor divider network.

Figure 26. Programmable Sequencing Control Circuit
Figure 27 shows a simple block diagram for the programmable sequencing control circuit. The application delays the enable signal, EN, of the external regulators (LDO x) in a linear order when the open-drain signal (SEQ) changes from low to high impedance.
The ADCMP392 has a defined output state during startup, which prevents any regulator from turning on if $\mathrm{V}_{\mathrm{CC}}$ is still below the UVLO threshold.

Figure 27. Simplified Block Diagram of a Programmable Sequencing Control Circuit

Figure 28. Programmable Sequencing Control Circuit Timing Diagram
When the SEQ signal changes from low to high impedance, the load capacitor, $\mathrm{C}_{\mathrm{L}}$, starts to charge. The time it takes to charge the load capacitor to the pull-up voltage (in this case, $\mathrm{V}_{\text {ref }}$ or $\mathrm{V}_{\text {CC }}$ ) is the maximum delay programmable in the circuit. It is recommended to have the threshold within $10 \%$ to $90 \%$ of the pull-up voltage. Calculate the maximum allowable delay by

$$
\begin{equation*}
t_{M A X}=t_{R}=2.197 R_{P U L L U P} C_{L} \tag{17}
\end{equation*}
$$

The delay of each output is changed by changing the threshold voltage, V1 to V4, when the comparator changes its output state.

To calculate the voltage thresholds for the comparator, use the following formulas:

$$
\begin{align*}
& V 1=V_{R E F}\left(1-e^{\frac{-t_{1}}{R_{\text {PULLUP }} C_{L}}}\right)  \tag{18}\\
& V 2=V_{R E F}\left(1-e^{\frac{-t_{2}}{R_{\text {PULLUP }} C_{L}}}\right)  \tag{19}\\
& V 3=V_{R E F}\left(1-e^{\frac{-t_{3}}{R_{P U L L U P} C_{L}}}\right)  \tag{20}\\
& V 4=V_{R E F}\left(1-e^{\frac{-t_{4}}{R_{P U L L U P} C_{L}}}\right) \tag{21}
\end{align*}
$$

The threshold voltages can come from a voltage reference or a voltage divider circuit, as shown in Figure 26.

First, determine the allowable current, $\mathrm{I}_{\text {DIV }}$, flowing through the resistor divider. After the value for $\mathrm{I}_{\mathrm{DIV}}$ is determined, calculate R1, R2, R3, R4, and R5 using the following formulas:

$$
\begin{align*}
& R_{D I V}=\frac{V_{R E F}}{I_{D I V}}=R 1+R 2+R 3+R 4+R 5  \tag{22}\\
& R 1=\frac{V 1 R_{D I V}}{V_{R E F}}  \tag{23}\\
& R 2=\frac{V 2 R_{D I V}}{V_{R E F}}-R 1  \tag{24}\\
& R 3=\frac{V 3 R_{D I V}}{V_{R E F}}-R 1-R 2  \tag{25}\\
& R 4=\frac{V 4 R_{D I V}}{V_{R E F}}-R 1-R 2-R 3  \tag{26}\\
& R 5=R_{D I V}-R 1-R 2-R 3-R 4 \tag{27}
\end{align*}
$$

To create a mirrored voltage sequence, add a resistor, $\mathrm{R}_{\text {mirror }}$, between the pull-up resistor (Rpullup) and the load capacitor $\left(\mathrm{C}_{\mathrm{L}}\right)$ as shown in Figure 29.

Figure 29. Circuit Configuration for a Mirrored Voltage Sequencer
Figure 29 shows the circuit configuration for a mirrored voltage sequencer. When SEQ changes from low to high impedance, the response is similar to Figure 28. When SEQ changes from high impedance to low, the load capacitor $\left(\mathrm{C}_{\mathrm{L}}\right)$ starts to discharge at a rate set by $\mathrm{R}_{\text {mirror. }}$. The delay of each comparator is dependent on the threshold voltage previously set for $t_{1}$ to $t_{4}$. The result is a mirrored power-down sequence.

Figure 30. Mirrored Voltage Sequencer Timing Diagram

The timing diagram for the mirrored voltage sequencer is shown in Figure 30.
Equation 18 through Equation 21 must account for the additional resistance, RMIRROR, in the calculations of the voltage thresholds. To calculate these new thresholds, see Equation 28 through Equation 31.

$$
\begin{align*}
& V 1=V_{\text {REF }}\left(1-e^{\frac{-t_{l}}{\left(R_{\text {PULLUP }}+R_{\text {MIRROR }}\right) C_{L}}}\right)  \tag{28}\\
& V 2=V_{\text {REF }}\left(1-e^{\overline{\left(R_{\text {PULLUP }}+R_{\text {MIRROR }}\right) C_{L}}}\right)  \tag{29}\\
& V 3=V_{\text {REF }}\left(1-e^{\frac{-t^{2}}{\left(R_{\text {PULLUP }}+R_{\text {MIRROR }}\right) C_{L}}}\right)  \tag{30}\\
& V 4=V_{\text {REF }}\left(1-e^{\frac{-t_{4}}{\left(R_{\text {PULLUP }}+R_{\text {MIRROR }}\right) C_{L}}}\right) \tag{31}
\end{align*}
$$

$\mathrm{R}_{\text {mirror }}$ provides the mirrored delay by prolonging the discharge time of the capacitor. The mirrored voltage sequencer uses the same threshold in Equation 28 to Equation 31 in a decreasing order. To calculate the exact value of the mirrored delay time, see Equation 32 through Equation 35.

$$
\begin{align*}
& t_{5}=-R_{M I R R O R} C_{L} \ln \left(\frac{V 4}{V_{\text {REF }}}\right)  \tag{32}\\
& t_{6}=-R_{M I R R O R} C_{L} \ln \left(\frac{V 3}{V_{\text {REF }}}\right)  \tag{33}\\
& t_{7}=-R_{M I R R O R} C_{L} \ln \left(\frac{V 2}{V_{R E F}}\right)  \tag{34}\\
& t_{8}=-R_{M I R R O R} C_{L} \ln \left(\frac{V 1}{V_{R E F}}\right) \tag{35}
\end{align*}
$$

## MIRRORED VOLTAGE SEQUENCER EXAMPLE

To illustrate how the mirrored voltage sequencer works, see Figure 27 and then consider a system that uses a $V_{\text {ref }}$ of 1 V and requires a delay of 50 ms when SEQ changes from low to high impedance, and between each regulator when turning on. These considerations require a rise time of at least 200 ms for the pull-up resistor ( $\mathrm{R}_{\text {PuLLup }}$ ) and the load capacitor $\left(\mathrm{C}_{\mathrm{L}}\right)$. The sum of the resistance of $\mathrm{R}_{\text {mirror }}$ and Rpullup must be large enough to charge the capacitor longer than the minimum required delay. For a symmetrical mirrored power-down sequence, the value of Rmirror must be much larger than Rpuluup. A $10 \mathrm{k} \Omega$ Rpulup value limits the pull-down current to $100 \mu \mathrm{~A}$ while giving a reasonable value for $\mathrm{R}_{\text {mirror. }}$ A typical $1 \mu \mathrm{~F}$ capacitor together with a $150 \mathrm{k} \Omega \mathrm{R}_{\text {MIRRor }}$ value gives a value of

$$
\begin{equation*}
t_{M A X}=2.197\left(\left(160 \times 10^{3}\right) \times\left(1 \times 10^{-6}\right)\right)=351 \mathrm{~ms} \tag{36}
\end{equation*}
$$

The threshold voltage required by each comparator is set by Equation 28 to Equation 31. For example,

$$
V 1=V_{R E F}\left(1-e^{\frac{-50 \times 10^{-3}}{160 \times 10^{3} \times 1 \times 10^{-6}}}\right)
$$

where $V 1=268.38 \mathrm{mV}$.
Therefore, $\mathrm{V} 2=464.74 \mathrm{mV}, \mathrm{V} 3=608.39 \mathrm{mV}$, and $\mathrm{V} 4=$ 713.5 mV .

Next, consider $10 \mu \mathrm{~A}$ as the maximum current (Idiv) flowing through the resistor divider network. This current gives the total resistance of the divider network ( $\mathrm{R}_{\text {DIV }}$ ) and the individual resistor values using Equation 22 to Equation 27, resulting in the following:

- $\quad \mathrm{R}_{\mathrm{DIV}}=100 \mathrm{k} \Omega$
- $\mathrm{R} 1=26.84 \mathrm{k} \Omega \approx 26.7 \mathrm{k} \Omega$
- $\mathrm{R} 2=19.64 \mathrm{k} \Omega \approx 19.6 \mathrm{k} \Omega$
- $\mathrm{R} 3=14.37 \mathrm{k} \Omega \approx 14.3 \mathrm{k} \Omega$
- $\mathrm{R} 4=10.51 \mathrm{k} \Omega \approx 10.5 \mathrm{k} \Omega$
- $\mathrm{R} 5=28.65 \mathrm{k} \Omega \approx 28.7 \mathrm{k} \Omega$

Resistor values from the calculation are nonindustry standard, using industry standard resistor values resulted in a new $\mathrm{R}_{\mathrm{DIV}}$ value of $99.8 \mathrm{k} \Omega$. Due to the discrepancy of the calculated resistor value to the industry standard value, the threshold of each comparator also changed. Calculate the new threshold values by using a simple voltage divider formula:

$$
\begin{equation*}
V 1=V_{R E F} R 1 / R_{D I V} \tag{37}
\end{equation*}
$$

where $\mathrm{V} 1=\frac{1 \mathrm{~V}(26.7 \mathrm{k} \Omega)}{99.8 \mathrm{k} \Omega}=267.54 \mathrm{mV}$.
Therefore, $\mathrm{V} 2=463.93 \mathrm{mV}, \mathrm{V} 3=607.21 \mathrm{mV}$, and $\mathrm{V} 4=712.42 \mathrm{mV}$.
Because the threshold of each comparator has changed, the time when each comparator changes its output has also changed.
Calculate the new delay values for each comparator by using the following equation:

$$
\begin{equation*}
t_{1}=-C_{L}\left(R_{\text {PULLUP }}+R_{\text {MIRROR }}\right) \ln \left(1-\frac{V 1}{V_{\text {REF }}}\right) \tag{38}
\end{equation*}
$$

where $t_{l}=-1 \mu \mathrm{~F}(10 \mathrm{k} \Omega+150 \mathrm{k} \Omega) \ln \left(1-\frac{267.54 \mathrm{mV}}{1}\right)=49.81 \mathrm{~ms}$.
Therefore, $\mathrm{t}_{2}=99.78 \mathrm{~ms}, \mathrm{t}_{3}=149.52 \mathrm{~ms}$, and $\mathrm{t}_{4}=199.4 \mathrm{~ms}$.
To calculate $\mathrm{t}_{5}$ through $\mathrm{t}_{8}$, use Equation 32 to Equation 35:

$$
t_{5}=-R_{M I R R O R} C_{L} \ln \left(\frac{V 4}{V_{R E F}}\right)
$$

where $\mathrm{t}_{5}=-150 \mathrm{k} \Omega \times 1 \mu \mathrm{~F} \times \ln \left(\frac{712.42 \mathrm{mV}}{1}\right)=50.86 \mathrm{~ms}$.
Therefore, $\mathrm{t}_{6}=74.83 \mathrm{~ms}, \mathrm{t}_{7}=115.2 \mathrm{~ms}$, and $\mathrm{t}_{8}=197.78 \mathrm{~ms}$.

## THRESHOLD AND TIMEOUT PROGRAMMABLE VOLTAGE SUPERVISOR

Figure 31 shows a circuit configuration for a programmable threshold and timeout circuit. The timeout, treset, defines the duration that the input voltage $\left(\mathrm{V}_{\text {IN }}\right)$ must be kept above the threshold voltage to toggle the $\overline{\text { RESET }}$ signal, preventing the device from operating when $V_{\text {IN }}$ is not stable. If $V_{\text {IN }}$ falls below the threshold voltage, the $\overline{\mathrm{RESET}}$ signal toggles quickly.

[^0]

Figure 32. Threshold and Timeout Programmable Voltage Supervisor Timing Diagram

During startup, the ADCMP392 guarantees a low output state when $\mathrm{V}_{\mathrm{CC}}$ is still below the UVLO threshold, preventing the voltage supervisor from toggling.

When Vin reaches the threshold set by the resistor divider (R1 and R2) and $V_{\text {REF, }}$, OUTA changes from low to high and starts to charge the timeout capacitor $\left(\mathrm{C}_{\mathrm{T}}\right)$. If $\mathrm{V}_{\text {IN }}$ is kept above the threshold voltage and the voltage in $\mathrm{C}_{\mathrm{T}}$ reaches $\mathrm{V}_{\text {ReF, }}$ OUTB toggles. If $\mathrm{V}_{\text {IN }}$ falls below the threshold voltage while $\mathrm{C}_{\mathrm{T}}$ is charging, the timeout capacitor quickly discharges, preventing OUTB from toggling while $V_{\text {IN }}$ is not stable.

In the condition that $V_{\text {IN }}$ is tied to $V_{C C}$, the circuit operates when $V_{C C}$ is more than the minimum operating voltage.

The threshold voltage $\left(\mathrm{V}_{\mathrm{TH}}\right)$ is configured by changing the resistor divider or $\mathrm{V}_{\text {REF. }}$. Calculate the threshold voltage by

$$
\begin{equation*}
V_{T H}=V_{R E F}\left(1+\frac{R 1}{R 2}\right) \tag{39}
\end{equation*}
$$

Timeout is adjusted by changing the values of the pull-up resistor or the timeout capacitor. To set the timeout value, determine the allowable current flowing through $\mathrm{R}_{\text {puluup }}$ and Ipuluup. When Ipullup is known, calculate Rpullup and $\mathrm{C}_{\mathrm{T}}$ by the following formulas:

$$
\begin{align*}
& R_{\text {PULLUP }}=V_{\text {CC } / I_{\text {PULLUP }}}  \tag{40}\\
& C_{T}=\frac{-t_{\text {RESET }}}{R_{\text {PULLUP }} \ln \left(1-\frac{V_{\text {REF }}}{V_{C C}}\right)} \tag{41}
\end{align*}
$$

## OUTLINE DIMENSIONS

COMPLIANT TO JEDEC STANDARDS MS-012-AA
CONTROLLING DIMENSIONS ARE IN MILLIMETERS; INCH DIMENSIONS (IN PARENTHESES) ARE ROUNDED-OFF MILLIMETER EQUIVALENTS FOR REFERENCE ONLY AND ARE NOT APPROPRIATE FOR USE IN DESIGN.

Figure 33. 8-Lead Standard Small Outline Package [SOIC_N]
Narrow Body
( $R-8$ )
Dimensions shown in millimeters and (inches)

## ORDERING GUIDE

| Model $^{1}$ | Temperature Range | Package Description | Package Option |
| :--- | :--- | :--- | :--- |
| ADCMP392ARZ | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ | 8-Lead Standard Small Outline Package [SOIC_N] | R-8 |
| ADCMP392ARZ-RL7 | $-40^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ | 8-Lead Standard Small Outline Package [SOIC_N] | R-8 |
